The Mining Magazine

PUBLISHED AT SALISBURY HOUSE, LONDON.

INDEX TO VOLUME XXIV.

FROM JANUARY TO JUNE, 1921.

EXPLANATORY NOTE.—Items in italics are names of books reviewed; illustrated articles are denoted by asterisks (*); the letters (*m.d.*) refer to notices of articles under the heading "Mining Digest."

PAGE

Abosso Gold ... Report ... 63
Acetylene Lamps, Makers of ... 165
Akim Alluvials ... 8
Alderson, V. ... *Oil-Shale Industry* ... 60
Alignment Charts ... J. A. P. Gibb (*m.d.*) ... 381
Alum and Sulphur at Tonopah ... (*m.d.*) ... 314
Aluminium in Engineering ... J. G. A. Rhodin (*m.d.*) ... 381
American Smelting and Refining Control ... 266
Ammonia Process, Haber's ... (*m.d.*) ... 314
Ammonium Sulphate Process, Feld's ... (*m.d.*) ... 314
Anaconda Company's Output ... 329
Anaconda Electrolytic Zinc ... (*m.d.*) 303, 378
Andean Geology ... J. A. Douglas (*m.d.*) ... 313
Anglo-Ecuadorian Oilfields ... 266
Anglo-Persian Oil Co. in Hungary ... 202
Anglo-Persian Oil Co. in West Australia ... 73
Anglo-Persian Oil Co.'s Concession in Newfoundland ... 10
Anglo-Persian Oil Co.'s New Capital ... 202
Antimony Oxide as a Pigment ... (*m.d.*) ... 121
Apatite-Magnetite Deposits of Dhalbhum, E. F. O. Murray *211
Apex (Trinidad) Oilfields ... Report ... 384
Aramayo-Francke Dividends ... 74
Arizona Copper Co.'s Metallurgy ... (*m.d.*) ... 252
Ashanti Goldfields Corporation ... 328
Associated Northern Blocks ... Report ... 256
Atkinson, J. B. ... Cumberland Iron Ores ... 96, 158
Aurora West United ... Report ... 383
Austral Oil Wells Co. ... 73
Australia, Gold Stealing in ... 259
Australian Coal Output ... 289
Australian Gold Output ... 264
Australian Mineral Output, 1920 ... 101

Bain, H. Foster, and U.S. Bureau of Mines ... 66
Balaghat Gold Mines ... Report ... 382
Bantjes, Exploration in ... 135
Barytes in Westmorland ... V. Bramall (*m.d.*) ... 191
Bauxite in West Africa ... A. E. Kitson (*m.d.*) ... 189
Berenguela Tin Mines ... Report ... 64
Bolivia's Case for the League of Nations ... 192
Borlase, W. H. ... Greenside Mine ... 281
Borneo, Petroleum in ... Emmons and Gruner (*m.d.*) ... 253
Borneo, Petroleum in ... J. Kewley (*m.d.*) ... 250
Boston Creek ... 32, 359
Bosworth, T. O. ... Mackenzie Oilfield (*m.d.*) ... 312
Botsford, R. S. ... Open-cut Mining ... *267
Brakpan Mines ... Report ... 320
Brakpan No. 4 Shaft ... 71
Brazil, Diamonds in ... D. Draper (*m.d.*) ... *372
Breathing Apparatus, Self-contained ... R. C. Smart ... 348
Brisbane Letter ... 353
British Aluminium ... Report ... 256
British Aluminium's Water Power ... (*m.d.*) ... 253, 381
British America Nickel Corporation ... 138, 225
British America Nickel Corporation ... (*m.d.*) ... 375
British-Borneo Petroleum ... 265
British Columbia, Copper Mining Position in ... 32
British Columbia, Gold Mining Position in ... 32
British Columbia Output, 1920 ... 159
British Controlled Oilfields ... 330
British Platinum and Gold starts Production ... 10
British West Africa Co., Collapse ... 137
Broken Hill Associated Smelters Fire ... 72
Broken Hill, Position at ... 72, 137, 201
Broken Hill Proprietary Steel Works Closed ... 137
Brown, J. Coggin ... Indian Iron and Steel Industry ... *339
Building Stones ... J. Allen Howe (*m.d.*) ... 122
Building Trades' Exhibition at Olympia ... 295
Bullfinch Proprietary ... Report ... 128
Bullfinch Proprietary, Management of ... 328
Bunker Hill, Electrolytic Zinc at ... 74
Bunker Hill Lead-Smelting Plant ... (*m.d.*) ... 122
Burma Corporation and Lead Smelters ... 258
Burma Corporation's Output ... 73
Burmah Oil New Shares ... 329

Cadmium, Separation of ... (*m.d.*) ... 122
Calcium ... (*m.d.*) ... 309
Calloose in Court ... 36, 73
Callow Process, Minerals Separation and ... 202
Cam and Motor Restarts ... 200
Camborne Geological Holiday Course ... 194
Camborne Letter ... 34, 100
Camborne War Memorial ... 2
Camborne War Memorial ... Hutchin and White ... 359
Camp Bird ... Report ... 317
Canadian Institute of Mining and Metallurgy ... 195
Canadian Metal Output, 1920 ... 100, 224, 330
Canadian Mint and Precious Metals ... (*m.d.*) ... 191
Canadian Oil Regulations ... 210
Cape Copper ... Report ... 64
Cape Explosives Works Debentures ... 327
Carbonic Oxide as a Poison ... 324
Carbonization, Low-Temperature G. H. Thurston (*m.d.*) ... 122
Carn Marth, Geology of ... (*m.d.*) ... 121
Cass Technical Institute, Sir John ... 258
Cassiterite, Flotation of ... (*m.d.*) ... 251
Cementation and Vein-Filling ... S. J. Lett ... 219
Cementation at Mazoe Dam ... (*m.d.*) ... 122
Cementation Process, Francois ... H. S. Ball (*m.d.*) ... 59
Cementation, Repairing Lens Collieries by ... (*m.d.*) ... 117
Central Mining and Investment ... 324
Champion Reef Gold ... Report ... 128
Champion Reef resumes Dividends ... 9
Charters Towers School of Mines ... 322
Chemicals, Prices of ... 47, 109, 171, 239, 301, 367
Chendai Consolidated ... Report ... 316
Chile, Gold Mining in ... L. Pitblado ... *27
Chillagoe seeks New Capital ... 9
China Clay Corporation ... 73
China, Quicksilver Mining in ... F. Trythall (*m.d.*) ... 187
Chinese Engineering and Mining ... Report ... 64
Chinese Engineering and Mining's Iron Enterprise ... 10
Chloridizing Roasting by Ramen Process ... (*m.d.*) ... 253
City Deep ... Report ... 318
City Deep, New Shaft at ... 133
City Deep Shaft ... E. H. Clifford (*m.d.*) ... *179
Clennell, J. E. ... Estimation of Phosphoric Acid ... 151
Coal ... J. H. Ronaldson ... 123
Coal, Flotation Process applied to ... (*m.d.*) ... 189, 190, 253
Coal in Great Britain ... Walcot Gibson ... 62
Coal in Tasmania, Prospecting for ... 163
Coal, Mineral Matter in ... R. Lessing (*m.d.*) ... 191
Coal Output, Australian ... 289
Coal Washing ... E. Prochaska ... 285
Cobalt Brasses ... (*m.d.*) ... 253
Cobalt Deposit near Selwyn, Queensland ... (*m.d.*) ... 253
Cobalt, Ontario ... 31, 99, 162, 225, 293, 358
Colemanite, Origin of ... (*m.d.*) ... 381
Colorado Oil-shales ... (*m.d.*) ... 314
Compressed Air for Power in Mines ... (*m.d.*) ... 252
Compressed Air in Mines ... (*m.d.*) ... 59
Compressed Air, Measuring ... J. L. Hodgson (*m.d.*) ... 190
Congo State, Aeroplane Service in ... 136
Consolidated Diamond Mines of South Africa ... Report ... 255
Consolidated Langlaagte Mines ... Report ... 318
Consolidated Mines Selection Dividend ... 135
Consolidated Mines Selection Meeting ... 327
Consolidated Mining and Smelting ... 356
Copper Assay, Fleitmann's ... (*m.d.*) ... 253
Copper in Steel ... (*m.d.*) ... 314
Copper Losses in Slags ... F. E. Lathe (*m.d.*) ... 56
Copper Mines Closed in United States ... 202, 329
Copper Production, World's ... F. H. Hatch (*m.d.*) ... 122
Copper Smelting in Japan ... (*m.d.*) ... 122
Coppers, The Porphyry ... 325
Cordoba's Property in India ... 264
Cornish Kaolin, Ltd. ... 329
Cornish Tin Mines Close-down ... 100
Cornwall, Pumping Difficulties in ... 202
Corundum in Transvaal ... A. L. Hall ... 126

PAGE

Costs, Records of Mining............A. E. Pettit (*m.d.*).... 314
Cottrell Precipitation Process..........(*m.d.*).... 185, 191, 381
Crown Mines ....Report.... 318
Crystallography ....J. B. Jordan.... 192
Cumberland Iron Ores, Genesis of...J. B. Atkinson.... 94, 158
A. A. Jones 96
J. D. Kendall 96
J. H. Goodchild 218
Cumberland, New Geological Survey for...................... 130
Cyanide Clean-up Problem........W. B. Chomley (*m.d.*).... 57
Cyanide Practice, Review of...........A. James (*m.d.*).... 122
Cyaniding in Ecuador.........................(*m.d.*).... 314

Daggafontein, Closing of 263
Daggafontein Finances 199
De-aeration of Solutions............H. A. White (*m.d.*).... 190
De Beers adopts Crushing Plant.............................. 7
De Beers Consolidated Mines ....Report ... 192
Deebook Dredging ....Report.... 128
Deep Mines, Conditions in, Orenstein and Ireland (*m.d.*).... 314
Desert, Adventures in the 197
Dhalbhum, Apatite Magnetite Deposits of...E. F. O. Murray *211
Diabase, Use of the Term 259
Diamonds, Alluvial in South Africa. F. C. Cornell (*m.d.*).... 59
Diamonds in Brazil...................D. Draper (*m.d.*).... *372
Diamond Mines, Depression at 136
Dolcoath Mine ....Report.... 62
Dolcoath's Finances... 36
Dolcoath's Future *21
Dolly Varden Mine 160
Draper, D. ....Diamonds in Brazil (*m.d.*).... *372
Drill-steel, Heat Treatment of ....(*m.d.*).... 380
Drill Steels, Sharpening ....(*m.d.*).... 306
Dua (Nigeria) Tin Fields ....Report.... 63
Dundee Coal ....Report.... 384
Durban Roodepoort Deep ....Report.... 317

Earth's Crust, Chemistry of ....(*m.d.*).... 118
East Indian Topography ...G. A. F. Molengraaf (*m.d.*).... 191
East Pool and Agar ....Report.... 254
East Pool, Accident at 329
East Pool, Developments at 26
East Rand Proprietary, Results for 1920 199
Economic Mineralogy ....T. Crook.... 220
Electric Plant at Easington Colliery ....(*m.d.*).... 59
Electric Smelting in Sweden.........J. Herlenius (*m.d.*).... 190
Electrostatic Deposition of Dust.......(*m.d.*).... 185, 191, 381
Electrostatic Precipitation of Sulphuric Acid......(*m.d.*).... 190
Ely, Nevada, Ore Deposits of............A. C. Spencer.... 125
Enemy Shareholdings in South Africa......................... 136
Esperanza Developments 10
Excess Profits Duty 131
Exploration Company ....Report.... 192

Falcon Mines, Position of 263
Falconer, J. D. ....Nigerian Geology.... *331
Falconer's Geological Survey of Nigeria.............. 200, 323
Fanti Consolidated 264
Farrow's Bank, Failure of 3
Federation Tin Company 328
Finsbury Technical College.............G. T. Morgan.... 97
Fire-damp in Gold Mines ....(*m.d.*).... 310
Flats and Sops in Furness...............J. D. Kendall.... *145
Flin-Flon, Mine Option on 266, 293
Flin-Flon Ore-body ....(*m.d.*).... *241
Flotation Litigation 202
Flotation of Cassiterite ....(*m.d.*).... 251
Flotation Process applied to Coal........(*m.d.*).... 189, 190, 253
Fluor-spar in Illinois ....(*m.d.*).... 191
Francois Cementation Process.........H. S. Ball (*m.d.*).... 59
Fremantle Smelter Closes 264
Fremantle Trading ....Report.... 64
Fresnillo, Mining Methods at ....(*m.d.*).... 380
Frontino and Bolivia Co.'s Output 330
Frontino and Bolivia Gold ....Report.... 64

Geduld Proprietary Mines ....Report.... 320
Geduld Reserves 71
Geevor Position 34, 138
Geevor Tin Mines ....Report.... 192
Geldenhuis Deep ....Report.... 319
General Petroleum of Trinidad 330
Geology of the British Empire............F. R. C. Reed.... 315
Geology, Political and Commercial..........J. E. Spurr.... 286
Geology, Text-book of.....................L. V. Pirsson.... 288
Geothermal Data of the United States.......N. H. Darton.... 192
Gersoppa Falls Power Scheme 329
Giew Position 35, 329
Ginsberg Liquidation 136
Glencairn Liquidation 136
Glencoe (Natal) Collieries ....Report.... 384
Globe and Phœnix ....Report.... 256
Globe and Phœnix Metallurgy ....(*m.d.*).... 308
Goch, New ....Report.... 383
Gold and Platinum in South Chile ....(*m.d.*).... 253

Gold Mining in Chile.........................L. Pitblado.... *27
Gold Output of World 2, 66
Gold, Precipitation of.............J. H. Johnson (*m.d.*).... 57
Gold Stealing in Australia 259
Golden Horse-shoe Estates ....Report.... 382
Goodchild, J. H. ....Cumberland Iron Ore.... 218
Goodchild, J. H., on Iron Ore.............................. 197
Gopeng Consolidated ....Report.... 316
Government Gold Mining Areas ....Report.... 320
Gowganda, Ontario 32, 359
Granby Consolidated 226, 356
Graphite for Crucible Use ....Dubs & Moses.... 192
Greenawalt Sintering Process ....(*m.d.*).... 183
Greenhow Hill 5
Greenland, Development of 322
Greenside Lead Mines................Interested........ 158
W. H. Borlase.... 281
Grenville Position 34

Haber's Ammonia Process ....(*m.d.*).... 314
Halberg-Beth Gas Cleaner ....(*m.d.*).... 381
Hampden Cloncurry's Position 8
Hampton Plains, Developments at 228
Hancock, R. T. ....Physical Basis of Tin-Dressing.... *80
Helium ....R. B. Moore (*m.d.*).... 191
Herb Lake Gold Deposit ....(*m.d.*).... 376
Hollinger Consolidated Gold Mines ....Report.... 256
Hoover, H. C., and Food Research 194
Hoover, H. C., as Secretary of Commerce 130
Huelva Sulphur and Copper ....Report.... 128
Hungary, Anglo-Persian Oil Co., in 202
Hydro-electric Power in Wales ....(*m.d.*).... 191

EDITORIAL

Notes 2
Gold Output for 1920; New Year's Honours; Libel Suits; Holland Park as a Site for London University; Memorial to Old Students of Camborne School of Mines; Vickers' Subscription to the Funds of Sheffield University; Britons in Russia; Bank Failures.

The Price of Metals 3
The slump in the Metal Market continues, and base metals are being generally sold below cost of production owing to the collapse of market speculations and to the lack of demand.

Conditions in West Africa 4
The mines in Nigeria and Gold Coast Colony are greatly inconvenienced by shortage of labour, caused by the competition of other industries and also of the Government railway-building operations.

Greenhow Hill 5
The Editor reviews a little book by Mr. Harold Bruff who tells of the character and lives of the lead miners in Yorkshire.

REVIEW OF MINING 7

ARTICLES

Kelantan and its Natural Resources ... *V. F. Stanley Low, M.Inst.M.M.* 11
The author gives an account of one of the lesser known States of the Malay Peninsula, and tells of his experiences there during a recent visit.

Dolcoath's Future 21
We print herewith the reports by Mr. R. Arthur Thomas, managing director of Dolcoath, and by Messrs. Bewick, Moreing & Co., on the proposed scheme for exploring the northern ground in depth for tin.

Gold Mining in Chile .... *Laurence Pitblado, M.Inst.M.M.* 27
The author writes of a neglected industry, the mining of low-grade deposits, which can be done under most favourable climatic and economic conditions.

EDITORIAL

THE world's output of gold during 1920 is estimated by Samuel Montagu & Co. at approximately £70,000,000 par value, as compared with £75,000,000 in 1919, £79,000,000 in 1918, £88,000,000 in 1917, and £95,000,000 in 1916. During the same years, the British Empire's quota was £48,000,000, £50,000,000, £51,000,000, £56,000,000, and £60,000,000. There is no hope of this steady and continuous fall being checked.

LAST month we mentioned that some of the shareholders in Brunner, Mond & Co. objected to the company devoting any of its funds to the cause of University education. Since then similar protests have been made in connection with the subscription of £10,000 by Vickers, Ltd., to the endowment of the University of Sheffield. Some shareholders evidently do not appreciate the fact that in these modern businesses with a scientific basis a supply of high culture and education is a prime necessity.

THE memorial to the old students of Camborne School of Mines who fell in the war is to take the form of the purchase of a school playing-field capable of providing accommodation for football, cricket, tennis, and hockey. It is hoped to raise £1,000 for this purpose. The battle of life is still often won on the playing-fields. Many of our readers will be glad to have the opportunity for encouraging this important part of the mining students' curriculum, and they should communicate with the treasurer of the fund, Mr. Stanley B. White, at the Mining School.

DURING the course of a libel action last month, the Lord Chief Justice said to the editor of the offending journal: "I am a little impatient when I hear that these articles are written because it is a public duty; you did it in the ordinary course of business." The case was connected with an engineering problem, and the editor honestly believed that he was exposing a public grievance. Nevertheless he had to pay £500 damages. Naturally all editors are pleased that the Lord Chief is vacating the position to become Viceroy of India.

AMONG the recipients of New Year Honours are Mr. Bernard Oppenheimer, of Brighton diamond-factory fame, who has been made a baronet; Mr. Ernest Oppenheimer, the leading spirit in the Consolidated Mines Selection Company, the Rand Selection Corporation, and the Anglo-American Corporation of South Africa, who is made a knight; and Mr. Henry Strakosch, managing director in London of the Union Corporation, who is made a knight in recognition of his services to South Africa in connection with monetary problems. It is also announced that a knighthood has been conferred on Mr. H. W. A. Deterding, managing director of the Royal Dutch Petroleum Company.

DISCUSSION as to the site for the new London University buildings has been reopened by the proposal that the Senate shall consider the suitability of Holland Park, which has just been advertised for sale. This site is much larger than that in Bloomsbury, offered by the Government, and it is much cheaper. It is in a quieter neighbourhood, and it is in the heart of an admirable residential quarter. Though not in the centre of London, it is easily accessible from all parts by rail and omnibus, while its close proximity to the Imperial College, the Museums, and other educational institutions in South Kensington is a feature much in its favour. The objection to Kenwood, in Hampstead, was that the means of access were poor. Holland Park does not suffer from this disadvantage.

LAST month Mr. E. A. Brayley Hodgetts delivered a lecture before the Royal Society of Arts entitled: A Retrospect of the Personal Influence of Britons in Russia. The influence to which the lecturer referred was largely that devoted to the expansion of trade and industry. Of particular interest to mining engineers was his reference to the Urquhart family, which we quote herewith. "Another benefactor of Russia was Mr. Thomas Urquhart, M.Inst.C.E., locomotive superintendent of the Grazi-Tzaritzin railway in South Russia, who died as recently as 1904. He introduced a method of burning oil-fuel in the Grazi-Tzaritzin railway, with the result that by 1884 this form of fuel had supplanted coal over the whole system. Mr. F. V. Urquhart was the actual inventor of the method adopted, which he described in a paper read before the Institution of Mechanical Engineers. It is unnecessary to expatiate on the benefits conferred not only on Russia, but on the whole world by this satisfactory practical solution of the use of oil re-

siduals, hitherto waste, as fuel. Another member of this gifted family is Mr. Leslie Urquhart. His herculean work in organizing the mining industry of Siberia and Russia on a colossal scale is too well known to need comment." We take the liberty of adding Mr. Brayley Hodgetts' own name to the list of distinguished English engineers who have done notable work in Russia.

SINCE writing last month on the question "What is a Bank?" there have been two regrettable failures of institutions that were not legitimately entitled to this designation. The failure of Farrow's Bank came with dramatic suddenness just before Christmas. This is one of the two types of so-called banks to which reference was made last month. It was clearly not so much a bank as a benefit society. Such institutions cannot afford to pay interest on monthly balances on the scale usually adopted by them. As for the application of funds, they are not able to secure first-class business in competition with the big firms, and if they rely on gilt-edged securities they are quite unable to make good the heavy depreciation. We are sorry for Mr. Farrow, for he did great service in earlier days in drawing attention to abuses in money-lending, and we are loth to believe that there have been any irregularities in the conduct of the bank. The leading banks have once more advertised their willingness to take small deposits. As regards the Post Office Savings Bank, the weak point of this institution continues to be its refusal to take more than £50 in a year and more than £200 altogether. After a depositor has reached this maximum limit, he has to transfer into Consols or some such security. Then his capital begins to shrink. It is probable that the average depositor who has transferred in this way has, during the past twenty years, lost nearly as much capital eventually as if he had put his money in the Cheque Bank, the Birkbeck Bank, or Farrow's Bank. Presumably this maximum was fixed originally at the express desire of the regular banks, and in that case it may be taken that the latter did not consider business below this limit as being profitable to themselves. With dearer money, these conditions are no doubt different nowadays. Following the stoppage of Farrow's Bank, the Chancellor of the Exchequer announced in Parliament that the question of "What is a Bank?" will have to be discussed and settled in the House of Commons. When this matter is taken in hand, it will be desirable to have the publicly-expressed views of bankers as to the removal of the limit on Post Office deposits. The British-American Continental Bank, formerly Hannevig's, which has also failed, was of the type which we had in mind when the editorial last month was written, where the particular abuse to which the word was put referred rather to its application in the names of financial houses or promoting companies pure and simple. Such a use is just as deceptive as in the other case, though it operates in different circles. Both classes of institutions will require an equally close scrutiny whenever the House of Commons makes its investigations.

The Price of Metals.

Since writing last month on the slump in the price of metals, the situation has become even worse, copper, lead, zinc, and tin all showing further substantial falls. The price of zinc is far below the cost of production even under the most favourable conditions, while the prices of the other metals are much below the average cost. Not only are the prices low, but sales are restricted owing to the dull times in all the consuming trades. Every now and then a slight rally is observed in quotations in lead, zinc, and tin, but it is much to be feared that the cause is merely bear covering. The American copper producers have not been able to tempt consumers by progressive cuts in quotations, and stocks are accumulating. The Anaconda company is not paying its customary dividend; as one of the directors said, "they have plenty of copper but no gold." Rumour has it that the "porphyries" are considering a general closure. In British Columbia the Britannia and Canada Copper mines have been closed, owing to the fall in the metal, and the Granby and Consolidated are severely restricting operations. The Broken Hill mines are in an unusually unfortunate position. Just as they had started work once more, after an eighteen months' strike, the low level of prices has made it necessary to pause and wait for prices at which the products can be sold at a profit. The Electrolytic Zinc Company at Risdon, Tasmania, has suspended production, which had reached 25 tons per day, but the construction of the plant is being continued, and the Mount Read & Rosebery mines are being developed and the ore tested. And many other contractions of operations could be instanced, as a result of the slump in prices.

Whenever a slump in metals occurs and operations of established mines are curtailed, proposals for the development of new proper-

ties are not considered. Readers of the MAGAZINE often write to inquire why this should be so, arguing that the dull times when sales of output cannot be effected profitably should be devoted to what may be called dead work. They point out that new properties are generally floated in boom days, and that by the time there is an output the prices have reacted and the expected profits are not realized. The answer to these inquiries and suggestions is that investment in mining operations is largely a matter of temperament and of availability of funds. When metal prices are high and profits substantial, the quotations of the shares of established companies are at a maximum. Then the promoter and speculator sell out and have the funds for the flotation of new propositions. On the contrary, when times are dull the share market is depressed, and holdings can only be realized at a big loss, if at all. If that is so with individuals, how much more must it be the case with the promoting companies, who have to take steps to prevent their balance sheets from suffering owing to the serious shrinkage in the market value of their securities! It is thus clear that only the individual who has a long pocket independent of the market in mining shares could possibly consider the investment of funds in new mining ventures during the dull times, and unfortunately such individuals are few and far between.

Conditions in West Africa.

During the last year or two the mining companies operating in the Gold Coast Colony and in Nigeria have found a difficulty in keeping their native labour forces up to full requirements. In Nigeria the companies have not only had to stand up against the competition for labour coming from other industries and from the Government, but they also have suffered internally from the action of a few of their members in offering higher rates of remuneration than those generally recognized as suitable in connection with tin-mining operations. All endeavours to arrive at some concerted plan of action in this matter appear to have failed so far. In the Gold Coast Colony the cocoa plantations always offer serious rival attractions to the native worker, chiefly for the reason that the cocoa and chocolate manufacturer is one of those fortunate folks who have control of their own markets and can pass on any increase in costs to the consumer, thus having a strong pull over the producer of metals. A more serious competition, however, has more recently arisen owing to the large public works undertaken by the Government, particularly in the way of new railway construction and the re-building of old railways. The Government gets the mines both ways. To begin with, it is a competitor in securing labour for its railway work, and then, after construction is completed, it arranges its haulage rates on such a system that they virtually constitute a tax on the mines for Government revenue purposes. At the meetings of four of the West African companies held in December, Ashanti Goldfields, Taquah, Abosso, and Prestea Block A, the chairmen have drawn attention to this unfortunate position with regard to labour, and have publicly asked the Governor and those in authority at home to treat their ventures, which are all sound, established industries, with rather more complaisance. It may possibly be said that it is bad form to criticize a Colonial Government on points directly in connection with the critic's own interests, but in connection with West Africa there need be no such hesitancy in alleging that there is something wrong somewhere, for the mistakes made in the matter of paper currency are so obvious to every one that it is permissible to presume a lack of infallibility on the part of those in control. Thus every business man will back the gold-mining companies in their appeal to the Government authorities for fair treatment.

Whenever the question of native labour arises in any of the British dominions, it is necessary to remember the perennial difficulty of treating the inferior races with reasonable kindness and justice. The Aborigines Protection Society keeps a sharp eye open for anything like slavery or forced labour. It is right that this should be so, for otherwise a few unscrupulous men might bring about a relapse to conditions prevalent a hundred years ago. On the other hand, many dependable and unprejudiced observers have advocated some beneficent form of forced labour, for their gorge has risen at the sight of the indolent male living on the results of female exertions. In Tanganyika Territory there appears to be some scheme on hand for organizing native labour, which by some people may be considered as bordering on the "forced." Here the question is of unusual difficulty, for the chiefs are naturally harsh and false to their word, and the German influence was in the same direction. Mr. F. S. Joelson's book, just published, gives a very fair statement of conditions there. He admits that much patience will have to be exercised before a better mode of living is inculcated, but he sees in the natural sociability and good humour of the native a means for ultimate improvement. In West Africa the conditions under which the native lives are not

unfavourable, and there is only an unproved suspicion that the chiefs exercise undue pressure in making their subjects work for the Government and for the British companies and settlers. Our own impression is that the West African native is not an unwilling worker, and that, as regards the mines, the general question of the treatment of inferior races does not enter into the question at all.

The mine managers would naturally take steps to modify their plans whereby to reduce the amount of labour required, if such a course were possible. In the present case Ashanti Goldfields is the only company that could so rearrange the methods, and even here it is only the metallurgical treatment that can be modified. The ore, as readers who remember Mr. W. R. Feldtmann's article in the MAGAZINE for May, 1916, are aware, consists of quartz containing free gold and auriferous sulphides and also much graphite. The practice for the last ten years has been to dry-crush, roast, and cyanide. This plan was found to give a substantially higher recovery than wet-crushing, amalgamation, and cyaniding of sand and slime, though the cost was slightly higher. During the last year or two the cost has greatly increased, largely owing to the higher price of wood and of spares in the dry-crushers. It is now considered advisable to rearrange the treatment and adopt wet crushing, concentration, and roasting and cyaniding the concentrate. In this way there will be a great saving in wood fuel, as a comparatively small bulk of concentrate will have to be roasted, instead of the whole ore. The smaller scale of other operations will also bring advantages in reduced costs. Moreover, there will not be the same likelihood of stoppages, entire or partial, owing to scarcity of labour and fuel. It is clear that the recovery will not be so good, but here it is probable that the Minerals Separation process will prove useful in not only increasing the extraction of sulphides but also in saving much of the free gold. In fact, Ashanti Goldfields is one of the two companies trying this application of the process, as mentioned in the speech of the chairman of Minerals Separation held last month. The result of this rearrangement of the treatment process will be that, though the recovery will be lower, the reduction in costs will be great by comparison, and the profit will be improved. Unfortunately Taquah, Abosso, and Prestea Block A are not able to adopt modifications in metallurgical methods, and they will have to rely solely on their efforts to induce the Government to take steps to give them a steady and regular supply of labour.

Greenhow Hill.

Greenhow Hill's in Yorkshire,
Some way from the Minster City.
The Nidd flows by on the northern side,
To the south is Wharfedale, rich and wide,
A breezier spot you never spied.
But when begins my ditty,
Nearly thirty years ago,
To see the miners suffer so,
Through depression of trade, was a pity.
Lead! At ten or eleven pounds a ton,
It was clear that the mines could not be run
At a decent profit for anyone;
So the men had to leave the ore and chats,
From fifty different raikes and flats——

This fragmental parody of Robert Browning's well-known lines will serve to introduce to our readers a little book just published entitled: "T'ill an' T'Oade Uns upuv Greenho'," by Mr. Harold J. L. Bruff. If it had not been for the foregoing introductory jingle, readers would probably have imagined that the title was in the Haussa or perhaps the Siamese language. As a matter of fact it is broad Yorkshire for "The Hill and the Old Ones up at Greenhow."* The mining operations at Greenhow Hill were described in the MAGAZINE for May last by Mr. W. W. Varvill, who gave a historical account of the fortunes and misfortunes of this old mining district, as well as details of the present scheme for reviving the industry. Mr. Varvill told us that this work of resuscitation was due largely to Mr. Harold Bruff, a resident in the neighbourhood, who is one of the engineers of the North Eastern Railway. The driving of an aqueduct tunnel to supply Bradford with water from new reservoirs in the upper part of Nidderdale had proved the continuation of the lead formations and veins in depth, thus warranting considerable capital expenditure in connection with new mining ventures. In this little book now published we find Mr. Bruff to be one of those few people of position who really try to understand the miners and other working men, and to appreciate the innate goodness of heart and honesty of purpose of the average worker. But he does blame the miner for not being able to regard his relationship to his work as having influence on anything or anybody but himself. That the miner should work only as long as it suits him personally is not taken as an indication of wickedness; but Mr. Bruff puts it clearly to him that this attitude is the chief obstacle to the restoration of an ancient industry. Perhaps the author will be able to instil in the minds of the men the true economic principle.

* York: T. A. J. Waddington, *Yorkshire News* Office, Mansfield Street; price 3s. [illegible]d. net.

Greenhow Hill is one of the highest villages in England, and stands on the limestone moors between the two beautiful valleys of the Nidd and Wharfe. It is distinctly breezy at all times, and in winter the snow-drifts are often alarming. Yet the miners belong to the cult of the open window, and thus escape the tubercular and other troubles characteristic of Cornwall and North Wales. They are also believers in good feeding, and they looked askance at the miner in their midst from Cornwall, who lived on tea, bread, and marge, and grilled his mid-day rasher of bacon under the boiler furnace, and who ultimately developed scurvy. Many of them are characteristically tall and strong, and Mr. Bruff, who is himself half a Norwegian, sees in them the strain introduced by settlers from among the old Norse raiders.

The limestone in the backbone of the Pennine Chain is full of underground water courses, and both water and air ebb and flow with eerie effect. Unexplainable noises give rise to many ghost stories, which generally take the form of visits from dead friends or of premonitory warnings of disaster. The existence of piskies or gnomes forms no part of their superstitions. On the other hand, the effective reading of a chapter of the Bible has served to allay the evil spirit and restore courage to the miners. Some of the ghostly appearances, however, are not based on uncanny sounds, for candles and clogs can be seen at times moving about, and of these there can be no physical explanation. It is possible that the belief in these visions has come down from the early days of Scandinavian influence. For instance, the "bar-gest," or ghost of a bear, is a spirit that haunts the falls in the upper Nidd, as the White Lady haunted the falls near Melrose, according to Sir Walter Scott in the "Monastery." Also the "telegbaster," the being that "flees about in t'mornins with a crooked neb," has a family likeness to the Norwegian "deilegast," a departed spirit that may easily be mistaken for an owl.

Mr. Bruft's book contains character sketches of many men and women thinly disguised under homely names, and many of their doings are in connection with mining operations. Naturally the tragic events recorded have to do with the inevitable accidents in mines, and in all cases some act of true heroism and thoughtfulness is recorded. Joss and Bin and Kit and A'nt Hannah are characters such as are found in the pages of Quiller Couch. Many of their adventures reflect the dangers of mining. For instance, Kit tells how he worked in a mine where it was the custom that one shift of men were let down 40 fathoms for their ten hours' work and could not be brought to the surface again until the other shift arrived in due course. Many a time the air became so foul that the candles went out and the men had to grope their way in the dark to the foot of the shaft to wait in the damp and drippings for their relief in due course. The worst of it was that they received no pay for these hours of wretched idleness.

In another part of the book, Henry tells how the older and more experienced men among the miners, who had also the responsibility of managers as regards following a vein or leader, used to sit on their clog heels underground, chewing their bacca, and turning over in their minds the various problems before them. To help their cogitations they played with lumps of clay between their palms, and it was necessary that the clay should contain no grit, as the grit would entirely discompose their train of thought. So important was it that the clay should be perfectly smooth, that old miners went out of their way to obtain the best qualities, and each man would carefully keep secret the source of his supply.

One of the most tragic stories of the many in the book refers to a blasting accident, where two young miners were blown to bits. Their fellow miners collected the remains to the best of their ability, and placed them in coffins. When the coffins were brought to the church to await burial, the parson refused entrance, because the boys had been christened by a lay preacher, though after a long argument the remains were allowed to rest in the porch overnight. Old Joss said he did not see why there should be such a fuss about Christians being received into a church under such circumstances, when black men and real heathens were allowed to see the sights at York Minster, St. Paul's Cathedral, and even Westminster Abbey.

Books on the human side of mining are so scarce that when they appear they are worthy of special attention. Mr. Bruff's book provided us with Christmas reading of the right sort, and it can be recommended to all mining men for perusal in the same spirit. As we have said, it is only a small book, but it is closely printed and full of good things. One day perhaps Mr. Bruff will feel encouraged to elaborate and expand, and to give illustrations and even maps, though, of course, maps are only a weakness of the Editor of THE MINING MAGAZINE and may not be really necessary.

REVIEW OF MINING

Introduction.—The general depression of trade is becoming accentuated and the prices of metals have fallen so low that mining operations are hardly profitable anywhere. The exception is gold mining, and here in many cases it is only the premium that preserves the mines from failure.

Transvaal.—The dividends declared by the Transvaal gold mines for the latter half of 1920 are given in the accompanying table. The rise in the gold premium and its comparative steadiness account for a notable increase in the profits. The advance in the working cost, which has been characteristic of the last few years, has slackened somewhat, but expenses are still on the up grade. Unexpected reappearances in the dividend list are Kleinfontein and Knight Central.

The total dividends declared by mines on the Rand during the year amounted to £8,314,300, as compared with £6,287,200 in 1919, £5,330,000 in 1918, and £6,556,000 in 1917. Of the total, £5,185,500 came from mines in the Far East Rand.

The north shaft at New State Areas has cut the reef at a depth of 3,578 ft. Here the reef is faulted and disturbed by numerous quartz intrusions, and the assay-value is only 1 dwt. over 6 in. It will be remembered that the south shaft cut the reef in October, and that the assay-value averaged 89·8 dwt. over 18·9 in.

The chairman of the Johannesburg Consolidated Investment Company devoted a large part of his address at the recent shareholders' meeting to the company's new ventures in coal-mining. The interests acquired are the Cape and Carlchew collieries, which have been amalgamated as the Consolidated Collieries, Ltd., the Witrand and the Springs collieries, in the Transvaal, and the Natal Cambrian and Burnside Central collieries, in Natal. Of these, the collieries in the Transvaal and the Cape, and the Natal Cambrian, are producers, but the scale of operations can be greatly extended. The Burnside is not yet producing. In order to facilitate distribution of output, the company has acquired the business of J. R. Macduff and Co., Ltd., and introduced new capital. The chairman's comments on the dilatory methods of the Government railways are likely to make those in authority sit up and take notice.

The report of the Rooiberg Minerals Development Co., operating lode-tin properties north of Pretoria, shows that the mill was closed from May, 1919, to January, 1920, during which time attention was devoted to development. From the period of resumption to the end of June, the mill treated 15,427 tons of ore, and 12,056 tons of accumulated middlings and tailings. The total yield of concentrates, including some won by washing alluvial ground, was 330 tons. The Blaauwbank property recently acquired has been abandoned, and a trial is now being made on the Weynek property. At the original mines no new ore-bodies have been discovered lately. The profit for the year was £7,663, and £9,000 was distributed as dividend.

Diamonds.—The De Beers Consolidated has adopted the crushing system for its blue ground instead of weathering, and recently ordered gyratory crushers capable of disintegrating 40,000 loads per day. It will be remembered that the Premier company employed crushing from the commencement, and thus saved a considerable lock-up of capital. At one time it was thought by many that crushing would injure and break the diamonds, but apparently this does not form an economic feature of the matter. The crushing plant at Bultfontein has already been completed and should start in March. The plants for the Dutoitspan and Wesselton mines will not be at work for eighteen months.

Congo State.—It is announced that the Union Minière is adopting the Garred Cavers system of employing pulverized coal in the blast in their copper furnaces, with the object of reducing the coke consumption. This process was described in the MAGAZINE for September, 1919.

Rhodesia — The dividends declared by Rhodesian mining companies during 1920 exceeded one million pounds, the figures being nearly double those of the year before, and more than £300,000 higher those of 1917, the previous highest figures. The premium on gold largely accounted for this increase, but asbestos production was also an important factor.

The Cam & Motor announces the starting of the reorganized crushing and concentration plant. The flotation section will be at work in a week or two.

West Africa.—The labour position at the West African gold mines has become worse lately, owing to the natives being provided with counter-attractions in the form of Government railway work. Reference to this matter is made in another part of this issue. At the Taquah mine the lode has folded upward, and it has been followed by rises for 250 ft. Drilling is now in progress to locate its continuance. At the Abosso, developments have been good recently, and it is therefore disappointing to find that, owing to shortage of labour, it has not been possible to keep the mill going full time. The Abosso company has recently acquired the property of the Wassau company adjoining on the north, and situated on the dip of the Abosso lode.

The Goldfields of Eastern Akkim, Ltd., one of the Tarbutt group, has issued a subsidiary called Akim Alluvials, Ltd., with a capital of £150,000, for the purpose of acquiring mining rights over gold and diamond alluvial deposits in West Africa. In the report by Mr. John Saxton it is stated that a "shaft has been sunk 26 ft. on kimberlite in yellow ground yielding half a carat per cubic yard at that depth."

Nigeria.—Last month we recorded that the Jantar had absorbed the Kuru Syndicate and Kuru South. The company has since issued its yearly report to September 30, from which it appears that a loss would have been made had not a refund been received of excess profits duty previously paid. At the meeting of shareholders the chairman said the company had £12,000 worth of tin concentrate unsold and very little cash. As it is not possible nowadays to obtain the financial help customary on such occasions, it becomes necessary to make an issue of £25,000 preference shares or debentures in order to put the company on a sound basis.

The Northern Nigeria (Bauchi) Tin Mines is considering the ways and means of raising the additional capital required for completing the Kwall Falls hydro-electric installation. This plant is costing much more than originally estimated, owing to the continued advance in the price of materials and labour. The sum named is £125,000. The company already has a large preference share issue, and has in addition a loan of £45,000 covered by a debenture, the latter having been raised in connection with the hydro-electric plant. It is doubtful whether the chief shareholders would be in a position to provide further funds by a reconstruction, but it may be possible to raise the money by the issue of further debentures. Another course is to postpone the completion of the plant until the money, metal, and share markets improve. The company has extensive proved lands that can be profitably worked by present methods. In fact the past year's output was 100 tons greater than that of the year before. So the policy of delay in connection with the new power-plant may be the best under the circumstances.

Australia.—It is unfortunate that the slump in metal prices should come just as the Broken Hill mines had resumed work after a prolonged strike. The advisability of continuing operations is being seriously considered, and some of the mines, at any rate, will close down. At Kalgoorlie another stoppage is reported, again owing to the lack of fire-wood. The whole community is also upset with railway and shipping stoppages.

The further rise of wages in the West Australian goldfields, as awarded by the Arbitration Court, will have a serious effect on the industry. There is to be an immediate increase of 3s. 6d. per shift in the minimum average wage, and the machine miners' rate is advanced 4s. 6d. per shift. The working week is to be 48 hours for surface employees, and 44 hours for underground workers. The shift in rises, and in wet shafts and winzes, is to be 6 hours. A fortnight's holiday on full pay is to be given annually.

A new bill is being introduced by the West Australian Minister of Mines relating to tributing operations. It provides that before any royalties are deducted from the gold won, the tributers must have received £3 per week per man.

The Hampden Cloncurry reports a loss of £49,031 during the half-year ended August 31, owing chiefly to the fact that the products on

hand at the beginning of the period were sold at lower prices than the valuation. During the half-year the yield was 2,070 tons of copper, containing 1,152 oz. gold and 12,473 oz. silver. All operations at the MacGregor group of mines have been discontinued,owing to the low-grade ores not being able to stand the increased mining costs. Since the above cable message was received another has come to hand announcing that all operations have been suspended owing to the low price of copper.

It will be remembered that the directors of Mount Elliott gave an option on the whole of the company's copper properties to Hayden, Stone & Co., of Boston, who sent Mr. Edwin S. Berry, of the firm of Yeatman & Berry, to see if the great reserves of low-grade ores could be worked to profit. He reported against the project, owing to the impossibility of concentration, and the option lapsed. Mr. W. H. Corbould, the company's consulting engineer, has since brought forward a leaching scheme, based on the practice at New Cornelia, Arizona. The company will require a large amount of new capital to carry out this proposal, and in addition it will be necessary for a railway to be built to Argylla and Mount Oxide. Railway construction in Queensland is in the hands of the Government, and as the latter cannot raise funds easily for any purpose the outlook for a railway is not bright.

According to the cabled report of the Mount Morgan company for the half-year ended November, the copper unsold and in process of refining amounted to 5,035 tons. This state of congestion is largely due to accumulations caused by the shipping strike and by a strike at the Port Kembla refinery. Consequently it is not possible to declare any dividend. During the period under review, 172,343 tons of ore was mined, of which 106,895 tons was concentrated, yielding 39,436 tons of concentrates, while the rest was sent direct to the smelters. The smelters treated 58,868 tons of ore and 34,396 tons of concentrates, and produced blister copper containing 3,431 tons of copper and 52,686 oz. of gold. The company announces participation, in association with the Electrolytic Refining & Smelting Co., of Port Kembla, in the formation of the Australian Fertilizers Proprietary, which has been incorporated with a capital of £500,000. The refining company desired to have its own source of sulphuric acid, and the opportunity presented itself to start an acid works on a large scale, using the acid in the manufacture of superphosphates. The fertilizer works is now in course of erection at Port Kembla, and the first unit, with a yearly capacity of 30,000 to 40,000 tons of superphosphate, is expected to be completed next July.

The Chillagoe Company handed over its copper properties and railway to the Queensland Government in 1919, and now only owns the Mount Mulligan coal areas. The shareholders have just agreed to the raising of new capital, which it is expected will be at the rate of 3s. per 10s. share, for the purpose of clearing off its indebtedness to the Government and of completing the coke-oven installation.

New Zealand.—It is announced that the Talisman mine is to be abandoned, and all underground plant is being withdrawn. This mine contained rich ore in narrow veins and made handsome profits over a series of years. A year ago the reserves came to an end, and subsequent exploration by diamond-drill has not disclosed any further deposits of value.

India.—The reconstruction of the Nundydroog company, to which reference was made in the November issue, has been successfully carried through. Shareholders have generally responded to the call, and for the few shares not taken up by holders there have been large inquiries from elsewhere.

Another favourable event in the Indian group of gold mines is the re-entry into the dividend list of Champion Reef, which has just declared a dividend of 4d. per 2s. 6d. share. The last distribution was the final dividend of 4d. for the year ended September 30, 1918.

Malaya.—In order to stabilize the local tin-mining industry, the Government of the Federated Malay States has fixed a minimum price of tin, the basis being 110 dollars per picul. It will be remembered that two years ago the Government took somewhat similar steps for protecting the industry, the plan then being to buy at the official quotation whenever there was a difficulty of selling in the open market. A committee has been appointed to inquire into the cost of production of tin in the Federated Malay States.

The Government report on tin-mining in the Federated Malay States during 1919 has only just been published, and most of the information is therefore rather belated. It is interesting to note that 68% of the tin output comes from mines under Chinese control, as compared with 74% in 1913. Also, of the 36,935 tons of tin exported, 5,137 tons was in the form of metal produced at native smelters, while 31,798 tons was contained in concentrates sent to the English smelters at Singapore and Penang. The native smelters appear to have secured a larger share of the ore than previously.

Newfoundland.—The Anglo-Persian Oil Company has received a concession from the Newfoundland Government giving it sole right for five years to prospect for oil in all ungranted Crown lands. The existence of petroleum at Parsons Pond on the west side of the island has been known for over a hundred years. From 1867 onward a number of projects have been started and many wells were sunk, but the venturers were generally short of capital, with the result that commercial failures were recorded. The petroleum is found at an unusually low geological horizon, the rocks containing it belonging to the Lower Silurians.

Mexico.—The fall in the price of silver is causing great concern among many of the mining companies operating in Mexico. The directors of the Mexico Mines of El Oro have decided for this reason to postpone the issue of new capital to which reference was made last month. It will be remembered that the object of the issue was to complete the purchase of a second property in which the company is already largely interested.

Another favourable cable has been received from the Esperanza mine at El Oro with regard to developments on the fifth level. During the week ended December 31, the north drive was extended 13 ft., in which the lode averaged 8 oz. of gold and 105 oz. of silver over 16 in. of width.

Colombia.—As mentioned in last issue, the first dredge of the British Platinum & Gold Corporation has started work, and the second is in course of shipment. It has been decided to defer the placing of the contract for No. 3 owing to the high prices asked for this class of work. Messrs. Inder, Henderson, & Dixon report that systematic prospecting of the Cimarronas property has been completed. The limits of a deep channel have been ascertained, as also have been those of some blocks of shallower ground. In the deep lead it is estimated that there are 1,828,406 cu. yd., averaging 12·265d. per yard, and in the shallow leads 328,052 cu. yd., averaging 17·839d. per yard, the price of crude platinum being taken at £12 per ounce. It is intended now to prospect on the other properties belonging to the company.

Venezuela.—The South American Copper Syndicate has been engaged in litigation in the United States owing to the New York buyers of the syndicate's products desiring to evade their contract. The contract was made early in 1916 and covered the eight years from 1918 to 1925 inclusive. One of the terms was that the buyers should provide the freight. Owing to the increased cost of freight and refining, the buying firm attempted to repudiate its obligations under the contract. The company won its case in the court of first instance. The buyers appealed, and the case was re-argued. News is now to hand that the company's case is upheld by the Court of Appeal. The judgment is of considerable importance to the company, for it thus is able to avoid the present heavy charges made by smelters and refiners.

Chile.—Owing to the low price of copper, the Poderosa mines are reducing the shipments of ore and work is being devoted chiefly to development.

China.—The Chinese Engineering and Mining Company is about to start an iron and steel enterprise in Chinwangtao, the port near the company's coal mines. The enterprise is to be conducted jointly with the Lanchow Mining Co., the Chinese-owned coal-mining company that works adjoining lands and sells its coal through the same organization. The iron mines are near the Yang-tse-kiang, and Mr. Frank Merricks has reported that they contain large quantities of high-grade ore. The companies have made a contract with the owners of the deposit to buy four million tons of ore. Other sources of supply are being investigated. Designs for a blast-furnace are in course of preparation by Mr. F. W. Harbord.

Spain.—The strike at the Rio Tinto mines has been settled, by the intervention of the Minister of War, after lasting six months, but there is still a good deal of unrest in various quarters.

Roumania.—The Court of Appeal has reversed the decision of Mr. Justice Darling, who awarded the Roumanian Consolidated Oilfields the sum of £1,255,513 as compensation for the destruction of their property during the war. The Crown contended that application for compensation should not have been made to the British Government but to the Roumanian Government. It must be confessed that the attitude of the Crown and the result of the appeal caused considerable surprise, for it was always understood, as recorded in our pages in October, 1917, that Sir John Norton-Griffiths was sent by the British Government to destroy the wells, and that he did so after protest from the Roumanian authorities.

Spitsbergen.—An expedition of scientists from Oxford University to Spitsbergen is in course of preparation. Among their number there will be geologists and paleontologists. Two parties are to go out in sealing sloops in June and July next. The expedition is to be conducted with commendable economy.

KELANTAN AND ITS NATURAL RESOURCES.

By V. F. STANLEY LOW, M.Inst.M.M.

The author gives an account of one of the lesser known States of the Malay Peninsula, and tells of his experiences there during a recent visit.

KELANTAN AND ITS PEOPLE.—The two least known or explored of the protected states of the Malay Peninsula are Kelantan and Trengganu. The states of the Malay Peninsula are so frequently spoken of as the "Federated Malay States" that perhaps it would be as well to state that only four of them are federated. British Malaya is divided into the British colony of the Straits Settlements (Singapore, Penang, Wellesley, the Dind-dings, and Malacca), the Federated Malay States (Perak, Pahang, Selangor, and Negri Sembilan), and five other protected native states (Kelantan, Trengganu, Kedah, Perlis, and Johore), all of which acknowledge Great Britain as suzerain. In each of the five last-mentioned states Great Britain is represented by an "adviser" appointed from the civil service of the Federated Malay States; and the native rulers of the various states are expected to follow the advice given by their respective "advisers." The Governor of the Straits Settlements is also High Commissioner for each of the native states, being represented in the Federated Malay States by a Chief Secretary, who resides at the capital, Kuala Lumpur.

There appears to be uncertainty as to the origin of the people generally classed under the title "Malays" who form the bulk of the population. By many these are thought to have come from Sumatra; but, no doubt, many people also came from Siam, Java, and the neighbouring islands. The so-called Malay is able to cultivate his land and grow rice, maize, fruit, and vegetables; he is a skilled boatbuilder and boatman; he can weave silk and cotton; but he seldom produces an output of any of these articles beyond the immediate wants of himself and his family; and so great has been the kindness of Providence in furnishing rich soil, favourable climate, abundant fruits, and fish-teeming rivers that the life of the ulu, or up-country, Malay is one of comparative calm, ease, and almost luxury. The Malay who has not come into much contact with members of other nations is by nature courteously polite, but shy; and nearly every Malay is a born liar, who finds no shame when his lies are exposed.

As a worker on the river, poling or paddling his native craft, the Malay is an untiring expert, and he is also good at jungle clearing; but he soon tires of regular employment unless it has something to do with engines or machinery. He is, therefore, of but little use for work on mine or plantation unless in charge of a launch or motor-car, of which he soon becomes a careful driver; and in these departments he frequently leaves his Chinese competitor far behind.

MAP OF MALAY PENINSULA.
Showing the Various States and Political Divisions.

Only a few of the true aboriginals—the Saki—still remain. The Saki, as found in the Eastern states, is, generally speaking, very shy and holds no converse with members of other races, be they white, black, or yellow. He does no cultivation, but leads a nomadic life, gaining his sustenance from roots, fish, and birds, the last of which he brings down with darts discharged from a blowpipe some seven feet in length. Being a nomad he builds only temporary shelters, composed of palm fronds placed in the ground in a circle with tips inclined toward the centre so as to form a low

shelter, in appearance like an upturned bowl. Sometimes the palm fronds are placed in a straight line so as to form a simple break-wind, the inclined and overhanging tips being sufficient to ward off the drips from the jungle of the heavy tropical dews. The Saki inhabiting the banks of the Nenggiri river are said to have become more settled. I have not come into contact with the Nenggiri Saki; but such Malays as I have met who have been far up that river have spoken of the Saki there as being well-developed men, skilful boatmen, and good workers.

HISTORY AND GOVERNMENT.—British Malaya is a land without history or historical remains. Europeans have lived on the coast for at least four hundred years; but until 1860 there was only one white man known to be resident inland. Such development as had taken place prior to recent years was due to Chinese adventurers, and, in a less degree, to the Siamese; the Portuguese and Dutch appear to have allowed the country to lie dormant. The time of entry of the Chinese is unknown; but the turn of the tide came when the British took definite action in 1873. Almost the first matter in the native states to receive attention was that of state finances. By abolishing many of the taxes on exports and by taxing the importation of opium, spirits, and such like; by charging rents for mining and agricultural lands, and by seeing that the money so obtained was properly expended, the financial chaos which previously existed was straightened out to such good effect that, as an example, the Federated Malay States are now become wealthy enough to make state loans to their neighbours, and at the end of 1918 had a surplus of over twelve million pounds sterling.

When, in 1903, the first British Adviser was appointed to Kelantan, which then belonged to Siam, he found everything political in a rotten condition. The ruling Rajah, through the plotting of his own family (the usual practice in Malaya) had lost practically all power of governing; such taxes as it was possible to gather were not used for the benefit of the state; and no accounts of expenditure were kept. Under an agreement with Siam, Kelantan in 1909 became an independent state under the protection of Great Britain. Since then the ruling native potentate has been raised in dignity from Rajah to Sultan and governs the state with the assistance of a Council and under the advice of a resident British Adviser.

Kota Bharu, the capital and seat of government, has two courts, the principal one being under the presidency of a British magistrate and the minor one under that of one of the Malay aristocracy. District Officers, appointed from the British side of the civil service of the Federated Malay States, attend to the magistracy of the country districts and reside at Pasir Puteh and Kuala Krai. The officers in charge of the Lands Office and of the Survey Department are British, as are also the Chief Police Officer and his Chief Inspector. Most of the clerical work is performed by natives from India, China, and Ceylon, assisted by a fair proportion of local Malays. The police force is composed of Sikhs and Malays. The Sikhs are purely military police; all civil police work is performed by Malays under Malay inspectors appointed by the Chief Police Officer. All inspectors must pass an examination in English before appointment. There are three British doctors, and one Chinese doctor holding British diplomas, who are assisted in the various native hospitals by trained dressers drawn from India and China. There is no hospital accommodation for white people except at the private hospital of the Duff Development Company at Kuala Lebir.

COMMUNICATIONS.—Kelantan has a coast line of 45 miles and an area of 5,870 square miles; its greatest width is perhaps 75 miles. The country is flat along the coastal district; and it is said that three distinct old sea beaches may be traced, showing the rapid encroachment of the land on the sea due to the silt deposited by the torrential flow of the rivers during the rainy season. At a distance from the sea varying from 10 to 20 miles the land begins to rise and then quickly becomes mountainous, culminating on the southern boundary in Gunong Tahan—the Forbidden Mountain—7,186 ft. above sea level. This is about the highest peak in Malaya. The state is well watered throughout its length and breadth by rivers. The main river, the Kelantan, runs approximately north and is formed some 62 miles inland by the junction of the Galas and Lebir rivers. The main tributaries of the Kelantan are the Sokor and Nal rivers; but these two are not nearly so important as the tributaries of the Galas—the Pergau and the Nenggiri—which enter that river some 80 and 92 miles respectively from the coast. The Lebir has tributaries of fair size in the San, the Sok, and the Rek.

The approach from the sea to Tumpat, the port of Kelantan, is bad, owing to the rapid encroachment of the land. A few years ago the custom house was situated on a coconut-grown island opposite the town of Tumpat and

not far from the mouth of the Kelantan river. In those days coastal steamers on the way from Siam to Singapore entered an eastern channel, anchored behind the custom house, unloaded and reloaded, and then proceeded to sea through the western channel. Now everything has been changed, for the monsoons have made a low sandbank of the island which has spread out to such effect as to have formed a lagoon across the mouth of the river, leaving only a small opening for the passage of launches and lighters. The custom house and the coconuts have disappeared; and steamers must anchor outside at a distance of at least two miles from the landing place. In the monsoonal season Kelantan has been cut off entirely from outside communication for three weeks or a month at a time by the heavy seas breaking at the mouth of the only channel available. It is difficult to forecast what will happen unless a monsoon of exceptional violence follows the example of some of its predecessors and washes a new channel or entirely removes the sand-bank, because the lagoon which has been formed is being filled so rapidly with silt from the river that even the shallow-draught launches which traverse the rivers already find it difficult to cross the lagoon from the river mouth to the Tumpat jetty.

A railway is under construction and will eventually connect the Siamese system with that of the Federated Malay States by traversing the length of Kelantan and making a junction at Kuala Lipis in Pahang. For carrying out the necessary extensions in Siam to connect with Kelantan, and also to make another such extension on the west coast, the Government of the Federated Malay States advanced four million pounds sterling to Siam. For a considerable time past trains have been running from Tumpat to Tanah Merah, 36 miles inland; and a branch line has also been completed from Pasir Mas on this line to the border of Siam, where a junction should have been completed by this time with the Siamese system. It will be eight years or more before a junction with Kuala Lipis will be made, as there is much tunnelling to be done between Kuala Lebir and the Pahang border. So strange is the policy of the Federated Malay States Government in some things that their railway department, which is carrying on the construction of the line in Kelantan, states that neither passengers nor goods will be carried beyond the present terminus, Tanah Merah, until the whole line to Kuala Lipis has been completed. Thus will the development of Kelantan be delayed by officialdom.

THE LEBIR RIVER, AT A POINT ABOUT 78 MILES FROM THE COAST.

Kota Bharu may be reached in six miles by rail and ferry from Tumpat or in eleven miles by launch or native craft. Above Kota Bharu the Kelantan river is navigable throughout its length at all seasons by light-draught launches and lighters, as are also the Lebir for twenty miles and the Galas for 20 miles above their junction at Kuala Lebir, so that one may proceed upstream some 82 miles by branching off at Kuala Lebir into either the Lebir or Galas rivers. Beyond that distance the rivers are broken by rocks, rapids, shallows, and sandbanks; and for the two months immediately preceding the rainy season are passable for only the lightest of native craft. During a great part of the rainy season, when the rivers may be expected to rise anywhere from sixteen to thirty feet above normal level, it is practically impossible for native craft to go upstream, because the flow of the river is too rapid for oars or paddles to be effective, and there is too great a depth of water for poling; the thick jungle prevents the passage of boats along the edges of the flooded area. Therefore anyone engaged in prospecting for gold on the upper Galas, or for tin near the source of the Nenggiri, could quite easily be cut off from efficient supplies of food and mining stores for four or five months in the year.

As Kelantan possesses only a very meagre mileage of roads, and as these roads are only lightly constructed and badly maintained, and are designed to serve the flat lands mostly planted with rice, very little development, from a mining point of view, can be expected until the railway has been opened, roads made, and tracks cut to districts now practically inaccessible.

The census of 1911 showed Kelantan to have a population of 286,751, of which 269,000 were Malays and 10,000 Chinese.

GEOLOGY.—Very little is known geologically of Kelantan; and there is no work published which deals with Malaya as a whole or the whole of any one state. Kelantan is so deeply covered with soil, so much of the country is dense jungle, and the outcrops of rocks are so few that geological examination and prospecting for minerals are difficult matters. The main backbone of mountains, which runs north-west to south-east down the Malay Peninsula, is composed of granite, and there are many subsidiary ranges east and west of this. It is stated that the Tahan range, on the boundary of Pahang and Kelantan, is composed of conglomerates, quartzite, and shale, while in Pahang conglomerate and sandstone ridges are found at the foot of the main granite range. A belt of limestone is said to cross the peninsula from Malacca to the coast of Kelantan; but the limits of this belt, if it exists, have not been demarcated. There are many outcrops of limestone; and limestone hills and cliffs, containing large caves whose floors are deep in the guano of bats, are frequently met with in Kelantan; but so little survey work and exploration have been done that the extent of the limestone belt is at present unknown. Even the maps which have been supplied by the Government have been found to be grossly inaccurate; and my own experience has been that the least inaccurate maps are those which were prepared by the Duff Development Company for its private use. The most reliable map I was able to purchase from the Government was, I believe, mostly compiled from one originally made by the Duff Company, to whom in all things relating to the opening up and development of Kelantan the present white population of the state owe many thanks, a fact which many of them seem to ignore or forget.

Apart from the limestones, quartzites, shales, and conglomerates already mentioned, one finds clays, slates, schists, sandstones, and granites, the last being predominant.

MINING OPERATIONS.—In spite of the difficulties of prospecting, the Chinese appear to have been through the country long ago; and at the only two places where lode-mining is known to have been attempted—near the Sokor river and at Kundor, near Pulai—the surface had already been prospected and sluiced for gold; but the lodes there had been allowed to remain otherwise undisturbed. In the neighbouring states of Pahang and Trengganu the weathered outcrops of such lodes as have been found to exist there had been worked, without exception, by Chinese or Siamese in the years long gone by; and many hold that the most successful method of lode-prospecting is to follow the old native workings.

As the population of Kelantan is mostly confined to narrow strips along the banks of the main rivers, and as the Malay, as a rule, is either afraid or disinclined to go far into the jungle, very little information is to be obtained from them with regard to anything in the country except in close proximity to their homes; but it is possible that, when the country has been opened up by the advent of the railway and the population has become denser, further old workings will be found which will lead to the opening up and development of large ore-bodies lying in country now given over to tigers, elephants, and panthers.

The Duff Company spent a large amount of money in prospecting and in dredging the river bottoms; but none of its mining ventures was attended with lasting success. It would appear that the dredges gave variable results, rich periods of work being much interspersed with very lean ones; the four dredges at work seem to have lacked efficient supervision from headquarters, and the gold returns to have been most erratic.

Map of the State of Kelantan.

The Author's Journeys.—A great deal of tunnelling and shaft-sinking was done by the Duff Company near the source of the Sokor river, on what are often referred to as the galena mines. Operations were carried on there until 1907. While awaiting the fulfilment of certain business negotiations with regard to a concession of two hundred square miles, which was the primary cause of my presence in Kelantan, I arranged a visit to these old mines. As the Sokor river enters the Kelantan river about midway between Tanah Merah and Kuala Lebir, I sent forward the leader of my party to engage men and boats and meet

me at the mouth of the river. As I was on the point of leaving Kota Bharu to join the expedition, word was sent down that the men who had been engaged were afraid to proceed when they found that the expedition was to traverse the "poison" belt—the bad man's country—where it is said that one can arrange for the death of an enemy for half-a-dollar and where most of the native potions and poisons are compounded. I happened to mention the matter to the Chief Police Officer, who sent a party of native police with me, and we proceeded upstream, engaged new men and boats, and started shortly after daybreak from the mouth of the river. We took the Duff Company's old route to the mine, poling up the Sokor river and then walking six miles overland. Estimates of the river distance were very variable, and, as before stated, the maps available very inaccurate. However, our boat journey occupied a good long day and a half; and, as the river at the time was fairly high, good progress was made until the middle of the first day. After that the river became a series of rapids, shallows, sandbars, and deep pools, which meant wading in the water a great part of the time, digging passages through the shallows, and all hands hauling the five prahus which formed our means of transport. It was no uncommon thing to find the bows of one's prahu lying in ankle-deep water, while the stern projected over the edge of a steep bank of granite sand in a depth of over fifteen feet of water. We reached our river destination during the second day and pitched camp; and our six-miles tramp next day brought us to the deceased mining camp. This tramp was over the old wagon road of the Duff Company; and, although then devoid of bridges and much overgrown with jungle, the track was in otherwise excellent condition. As far as jungle growth was concerned, our way had been made easy by an adult and a baby elephant who had evidently traversed nearly the whole of the road the day before and whose beds of the previous night we passed on our journey. My natives were interested, but not afraid, when we met with the elephant tracks. It was not until we crossed the spoor of a sladang (wild buffalo) that I had difficulty with my bearers, for the sladang is regarded as the most dangerous animal in the Peninsula. It is a matter of common report in the East that he who goes out to seek sladang must keep a watch to the rear as well as to the front, the sladang becoming the hunter instead of the hunted if sufficient care is not exercised.

Various tunnels into the hillsides were noted; but all that remained of the former main engine shaft was a jungle-covered hole and some rotting timber. History relates that after the mine had been closed, and even before the last of the stores had been carried to the river bank, the Malay natives had swarmed in and stolen every bolt and piece of iron from the headgear, even going part way down the shaft in search of bolts, etc.

No galena could be seen on any of the old dumps we were able to find; but records show that a parcel of about 57 tons was bagged and sent to the smelters just prior to the closure of the mine. The dumps examined showed that the bulk of the material mined must have been of a pyritic nature, and the records also show that 80 tons of such ore was dispatched about the same time as the galena. One of the old assay books discovered at Kuala Lebir showed the large amount of exploratory work which had been carried out, and that as the work proceeded the ground was regularly sampled and the results carefully tabulated. Most of the assays from the "galena deposit" show gold and silver values only; and some of these are of considerable richness. For example, the following values are taken from a width of ore varying from two to five feet: Gold 64·8 dwt., silver 1·6 oz.; gold 38·4 dwt., silver 2·3 oz.; gold 44·0 dwt., silver 4·0 oz. The following assays are recorded from "Manson's deposit": Gold 1·6 dwt., silver 4·9 oz., lead 12·5%; gold 2·8 dwt., silver 8·2 oz., lead 36·0%; gold 1·6 dwt., silver 3·3 oz., and lead 14·5%. The records also mention the diamond-drilling of vertical holes in the slates; but encouraging results do not appear to have been obtained. It would seem that the whole mining proposition at this place was killed by bad transport arrangements. A road from the Kelantan river to the Sokor mines, say, twenty miles in length, and then extended to the Pergau river, say, another five miles, would not only have served the mines then being worked, but would have opened up a most promising belt of country extending up to the Tomo (Siam) alluvial goldfield. In spite of the fact that labour was considerably cheaper in 1907 than it is to-day, it cost the Duff Company approximately £80 to bring a moderate-sized boiler from the mine; and the smaller items of machinery, weighing from 8 cwt. to 1 ton, were contracted for at a rate of about 3s. 10d. per cwt. The slowness of river transport may be gathered from the manager's statement that loaded prahus which had left the head of the river on the Tuesday could not be expected back before the following Saturday.

My return down stream in our lightly-laden

prahus and with the channels dug on the up journey still available was comparatively rapid.

Upon another occasion I travelled on foot from the Kelantan to the Bertang river, a tributary of the Sokor, and found native mercury in the bed of the stream for quite a considerable distance in the Duff Concession. Later on I took an expedition up the Sokor river, where I was informed that quicksilver could also be found, for, if the metal could be found in both rivers, it meant the probability of an extensive mercury-bearing belt. On this occasion we travelled up the Sokor to our old river camp, but, the river being lower this time, we were forced to leave our largest prahu part way up and finish our river journey in relays. Arrived at our destination we set out for the spot where our guide said he had found mercury before; but none was to be found on this occasion, and it turned out that our guide had not been upstream to the supposed spot for at least eighteen years. He had with him a specimen of gålena which he said he had found in a hole 8 ft. deep some twenty-two years before, and was much incensed because I would not go with him to search for that 8 ft. hole which, according to the location given by him, must have been within the area afterward prospected and worked by the Duff Company.

Our last night at the Sokor was somewhat unpleasant, as the river began to rise and, having left our largest prahu some distance down stream, we had not sufficient carrying capacity for the whole of our men, kit, and provisions. We were therefore faced by a raging torrent on one side and a jungle infested with leeches and wild beasts on the other, and of these the leeches were the worse, while the rain was coming down as only it can come down in the tropics. However, we managed to hang on until daylight, when we built some bamboo rafts and floated away on the tide of the flooded river.

I made expeditions to other places where tin was supposed to exist within easy reach, but found, as a rule, only iron sands.

Just before the wet season was expected I set out with my guide in two prahu-dowds for the upper waters of the Galas in search of that Golconda of Kelantan, the Kundor mines. A prahu-dowd is the largest form of native up-river boat; ours were about 50 ft. long and 5 ft. wide, having a covered-in living-room in the centre about 14 ft. long but only $4\frac{1}{2}$ ft. high. Each was poled along by four Malays under the direction of the helmsman, who steered by means of a long oar lashed to the stern.

Prior to setting out on this expedition I went to Kota Bharu and asked the British Adviser whether any of the land up the Galas river had been granted for mining purposes. The British Adviser referred me to the District Officer up-river at Kuala Krai. An inquiry from the said District Officer received a reply that there were no papers in his office which showed that any of the land had been alienated for mining and that therefore all the land was open to me; but he advised me to take out a prospecting licence before starting. A Kelantan prospecting licence states clearly the location of the area to be prospected; but, as neither my guide

A Road at Kota Bharu

nor I knew the exact location of the Kundor mine, but were to be met by local men sixty miles above Kuala Krai who were to take us to the spot, it was impossible for me to take out a prospecting licence at that moment; but I agreed to send a special messenger down for a licence as soon as I had located the old workings. This I did, applying for an area of 4,000 acres. I was away with my expedition for a month, living and travelling in my prahu, and after having done some track-making and opening-up of the prospect, was compelled to return on account of the serious illness of my guide and also by the rapidly-approaching rainy season. On my arrival at Kuala Krai the District Officer informed me that after my departure the British Adviser had sent him some papers which tended to show that the

land for which I had applied had already been alienated and was not therefore available. My protest to the British Adviser brought the absurd reply that he was inclined to think that if I had obtained my prospecting rights before proceeding upstream from Kuala Lebir I should have avoided this loss of time and money.

My river journey of seventy miles from Kuala Krai to Pulai took sixteen days; and I had not travelled very far above the junction of the Pergau river before the difficulties of transport became apparent. The river had become impassable for anything but light-draught prahus; we encountered rapid after rapid, up which our prahus often had to be dragged with long ropes; and through many rocky and sandy places we had to dig channels for our craft.

The Chinese town of Pulai, which is known to have existed for over a hundred years, is a great contrast to the Malay kampongs with their jungle-constructed houses. In Pulai the houses are two and three storeys high, the thick walls being constructed of a lime concrete of rounded pebbles and river sand. The natives mostly make their living from alluvial mining; but the Kelantan Government gets very little in the way of taxation from the district, as most of the traffic is by foot over the border into Pahang. Formerly a Malay police inspector and several police were stationed at Pulai to collect dues; but they are reported to have spent most of their time in gambling, and when the barracks were being burned to the ground the Chinese residents say that the Malay police prevented them from attempting to extinguish the flames or salve the books and records, all of which were lost.

The Pulai Chinese are the remnant of a much larger population of the past. Some hundred years ago the ruling Rajah of Kelantan made over to his son the taxes on rice; these the Pulai Chinese refused to pay and, when the Rajah's son came to enforce the payment, they killed him. In revenge for this a punitive expedition was sent, with the result that most of the Chinese were killed, the Galas river ran red with blood, and was afterwards blocked by rotting corpses. Only a few of the residents escaped by hiding in the jungle; and those are said to be the ancestors of the present population. I had a number of Chinese working for me at Kundor and, although only one or two of them could speak Malay, we soon came to an excellent understanding. I found them a hardworking, jolly, capable crowd, and eight of them worked my prahus down-stream for me as far as Kuala Lebir, that being much farther than they had ever been away from Pulai before.

Kundor proved to be about eight miles down river from Pulai; and an inspection showed that much alluvial gold must have been won there. The Chinese had constructed several miles of water-races, and in some cases they had cut these for a depth of 15 or 20 ft. through the granite. The property had been worked by a Dutchman in more recent years, and he had done a fair amount of tunnelling and shaft-sinking before his death. The reputedly richest portion of the property was at the junction of the granite and the slates, and I made arrangements with the Pulai Chinese for the opening up and repair of the old workings at the conclusion of the approaching wet season, only to find on my return to Kuala Krai that the ground was not available.

Coming down stream I stopped, inspected, and sampled several quartz outcrops of good appearance with a view to a return visit at a later date.

The occurrence of a tin lode was rumoured on the border of Kelantan and Trengganu, and it is possible that such lode may exist, for in the state of Trengganu the privately-owned Bundi tin mine is reported to have given good returns to its owner. The neighbouring state of Pahang gives the only other example of lode tin mining on a large scale in Malaya. In Pahang the Chinese and Siamese are known to have worked the soft outcrops of at least forty lodes. These lodes are in the slates near the junction with the granite, into which they sometimes penetrate. In Trengganu wolfram veins are found in formations of quartzite, schist, and shale overlain by clays. The veins are worked only down to old water level, below which the sulphides of iron, copper, and arsenic occur. The ore, as sent away, contains 70% of tungstic acid. Wolfram found in the Federated Malay States is associated with tin; in Trengganu wolfram is found alone.

Alluvial tin is found in limited quantities in Pahang, Trengganu, and Kelantan; and it is a surprising fact that so much alluvial tin, shed from the range which forms the backbone of the peninsula, should, so far, have been found on the western side and so little on the eastern side of the range. When it is remembered that the Malay States have produced tin to the value of £180,000,000, the small proportion obtained from the eastern states gives much food for thought.

RUBBER INDUSTRY.—One cannot remain long in Kelantan without being impressed with the value of the land as a rubber producer.

There is plenty of virgin jungle, good loamy soil with good depth of humus, and light rolling country with easy drainage; there is no great variation in temperature to affect the flow of latex, and a reliable and generally well-distributed rainfall is assured. Growers state that rubber trees come into bearing six months earlier in Kelantan than in the western Malay States. At the conclusion of my mineral excursions I explored a considerable area of the country, finally demarcating some ten thousand acres for rubber planting. This involved living among the up-river Malays for a considerable period and the cutting of some thirty miles of tracks and survey lines.

In clearing the virgin jungle, Malays are generally employed, and carry out the work most satisfactorily. The jungle, though dense, does not carry a large number of trees of large girth to the acre; most of the jungle is "secondary." The Malays say that fifty years ago the whole country was devastated by a tornado and every tree was rased to the ground; that fire then got into the fallen jungle; and that Kelantan was on fire from end to end, men and animals being driven into the rivers by the heat and smoke. If this statement is true—and some of the older men say they can remember the conflagration—the comparative sparsity of big timber can be easily understood.

The planting of the rubber trees and all subsequent work is best performed by Tamils, Chinese, or Javanese, all of whom must be imported from their native countries.

Rubber trees should give at least 200 pounds of latex per acre for the first year of tapping, increasing yearly by 50 pounds per acre. A rubber estate should show a profit on its second year of tapping. Of course the crop of latex will vary with the quality of the ground and the care bestowed upon the estate. At the Pergau estate in Kelantan the average output is about 415 lb. of latex per acre tapped; but some of the best land gives 660 lb. per acre. Costs of production will vary with location, nature of land, and efficiency of management. Owing to the absence of transport facilities in Kelantan, costs may be expected to be higher for the time being than those in the western states, where some of the best estates have been able to produce at as low a cost as 23, 24, and 25 cents per lb., and the average of the best is 35 cents or about $9\frac{4}{5}$ pence per pound. The costs on many of the estates are, of course, much higher than these. In Kelantan the lowest costs are obtained at the Bagan Estate, where rubber is produced at an all-in expenditure of 29 cents per pound. Owing to the situation of the estate and the ability of the management, Bagan is able to use Malay labour in all branches of the estate work, proving thereby an exception to general Malayan enterprises. The Taku Estate of the Duff Development Company is producing rubber at the very satisfactory cost of 34 cents per pound.

Other Industries.—For their own immediate consumption the Kelantanese grow a fair quantity of tobacco, and an increase in this industry might be encouraged with advantage by working somewhat on the lines of the Borneo practice. The tobacco grown is not of high grade, but there is a ready sale for it among the natives of the surrounding countries. In Borneo the landowner lays out $1\frac{1}{2}$ acre for each native to cultivate and supplies him with tobacco seed. The native raises the tobacco and gathers the leaf, which is bought from him by the landowner in its green condition at twenty dollars per picul ($133\frac{1}{3}$ lb.). As a Malay should produce fifteen piculs from his acre and a half of properly cultivated land, he should be able to make three hundred dollars for eight months' work on his patch. The cost of shredding, drying, fermenting, and curing should amount to a further expenditure of forty-five to fifty dollars per picul, and the

A Kelantan Sea Beach

finished article can be sold for about one hundred and twenty dollars per picul.

Although some of the world's finest copra has been exported from Kelantan, coconut growing on a large scale has not been very successful up to the present time. The excellent sun-dried copra which the natives produce comes from their small kampongs where the trees thrive on the refuse, animal manure, and other filth which usually surrounds native habitations.

FINANCE.—The last annual report of the Kelantan Government showed the revenue collected to have amounted to £112,000, including land revenue £21,000, levy on imports and exports £31,700, and profit from the sale of chandu (opium) £29,000. Half of the export revenue of £17,000 was obtained from rubber, 10% from betel nuts, 17% from copra, and 9% from cattle. Heavy export duties have often been placed on produce in order to prevent the natives from bringing themselves into a condition of semi-starvation. Chinese traders used to travel throughout the country, reaching even the remotest kampongs, buying up cattle, fowls, ducks, rice, dried fish, &c. The Malay, having but little insight into external trading, was disposing of all his animals and birds, leaving himself no means of replenishing his stocks; he even sold his agricultural cattle and then had no means of cultivating his rice. Owing to the high export duties imposed, the exports of livestock are now mainly composed of pigs, pork being forbidden as an article of diet for the Malay. Rubber stood at the top of the list of exports, being two-thirds of the total value of £425,000. The imports were valued at £300,000.

CLIMATE.—The highest temperature recorded was that of 98° F. in Kuala Lebir in 1914, and the lowest was 62° in 1913, also in Kuala Lebir. At the sea-coast the mean maximum and minimum temperatures may be taken at 90° and 71°, while 60 miles inland they may be taken at 96° and 64°. The mean temperature throughout Kelantan is about 79° or 80°. In Kuala Lebir the annual rainfall taken over a number of years shows a variation between 74 and 136 inches; records in Kota Bharu show 95 to 165 inches with a maximum fall of 13·43 inches in 24 hours.

The wet season is distributed over November, December, and January when the relative humidity rises to a maximum of 90%. The wet season is immediately followed by the dry months of February, March, and April, in which the mean relative humidity is about 80%.

Living in the jungle, one is impressed with its stillness and quietude. No birds are to be seen except in the topmost branches of the highest trees. Occasionally a flock of monkeys is heard dashing away overhead, and in the early morning one may sometimes disturb a deer or wild pig. The air is still and breathless; there is never any wind. The morning often shows the tracks of elephants, tigers, and panthers which have not been far distant; but it is seldom that any of these animals is seen, and very few residents of the Malay States have been close enough to get a shot at a tiger. For a native to be attacked by a tiger on the east coast is unknown; but on one of the estates about 35 miles from Kuala Lumpur the toll of natives killed by tigers during the past twelve years has been quite a heavy one. This is attributed to the closer settlement of the district having driven the natural food to the tiger —the pig—away. Unlike the remainder of the Malay States, Kelantan is entirely free from crocodiles and bathing is therefore possible in all waters. Elephant hunts occasionally take place, and I visited one of the stockades into which they are driven, then in course of construction near the source of the Rek river. The animals are tamed and trained within a few weeks of their capture.

CONCLUSION.—In my exploration and in my various excursions I received much assistance from the officers of the Duff Development Company, the Chief Police Officer, the Government Survey Department, and District Officer Monk. Had it not been for the kindly offices of these gentlemen my way would have been much harder and my operations delayed; but I was deeply disappointed by the short-sighted policy of the highest Government officials who, as soon as I made application for rubber lands, gave notice of the imposition of higher rates and rents. An appeal against such imposition was upheld when placed before the Governor of the Straits Settlements; but restrictions introduced with regard to the employment of labour and the growing of food-stuffs made it so evident that enterprise from outside was not welcome that it was decided to withdraw entirely from a venture which would have included the opening up of 10,000 acres of agricultural land at an estimated expenditure of over £400,000 in a country sadly in need of development and of the introduction of capital.

[In connection with the foregoing article, readers may be reminded that the neighbouring State of Trengganu was described by Mr. Henry Brelick in the MAGAZINE for November, 1915.—EDITOR.]

DOLCOATH'S FUTURE.

We print herewith the reports by Mr. R. Arthur Thomas, managing director of Dolcoath, and by Messrs. Bewick, Moreing & Co. on the proposed scheme for exploring the northern ground in depth for tin.

FOR some time it has been known that the ore supply in depth at Dolcoath has been failing, and that the engineers are in favour of exploration laterally. The concrete proposals are now published, and the main points are given herewith. Briefly the proposal is to run a cross-cut at depth northward from the Williams vertical shaft in order to test the Roskear lodes at points below the deepest level of the old workings. The Roskear lodes were profitably worked for copper until forty years ago. At that time the copper gave out and tin put in appearance. The problem now is to test the lodes for tin at depth. It is expected that the cross-cut will also reveal information relating to south-westerly continuations of lodes worked at East Pool and South Crofty.

Mr. R. Arthur Thomas's Report.

It has not been possible for some time past to record any satisfactory results from the operations at Dolcoath, and it has been found necessary to greatly curtail the scale of working pending the consideration and determination of the future policy. In June last the bottom workings were abandoned and the pumping plant and sundry appliances have been successfully withdrawn from the 550 fm. level.

Having regard to the improbability of any immediate profitable developments on the main Dolcoath series of lodes sufficient to retrieve the position, new work must be embarked upon and capital provided therefor to restore the mine to its former importance as a profit-earning undertaking. This result will, I confidently anticipate, be realized if the following scheme of development can be carried out, that is, to drive a cross-cut from the Williams shaft north at the 338 fm. level to intersect the various lodes shown in the accompanying plan, and which have not been worked by this or any other company to such a depth. The plan shows the Dolcoath lode series and the projected position of the various lodes to the north, which will be intersected by the proposed cross-cut. The reasons for my unhesitatingly recommending the driving of this cross-cut, and my belief that in so doing the company will again become a profitable as well as large undertaking, are as follows:

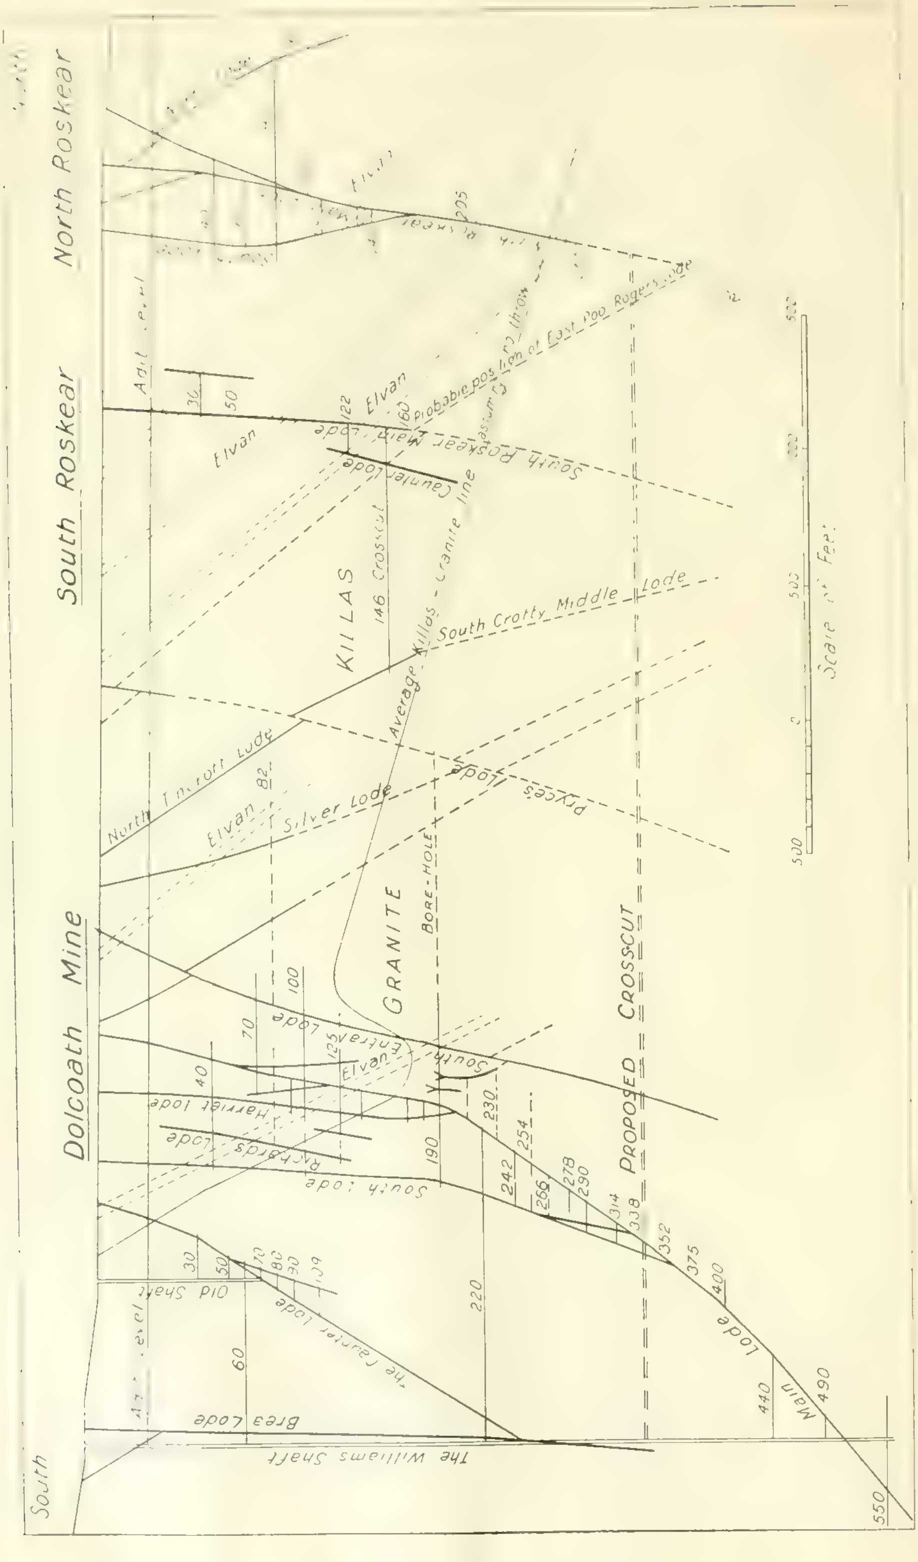
(1) Before the South and North Roskears, as well as the East Pool (Rogers) lode, lying between these two lodes, would be intersected, the important Tincroft and Crofty series of lodes would be met with, and also the various other lodes, of possibly less importance (forming a part of the series referred to), at less than half the distance of the total length of the cross-cut, which is estimated to be 4,420 ft.

(2) The mines to the north of Dolcoath, namely, South Roskear, North Roskear, and the Setons, slightly to the west, were large producers of copper in the killas, as was also Dolcoath in the approximately parallel lode series in the killas overlying the granite in which the Dolcoath main series of lodes have been so remarkably consistent producers of tin to a far greater depth than has been reached elsewhere in the country. None of the lodes in the northern areas referred to has been explored in the granite.

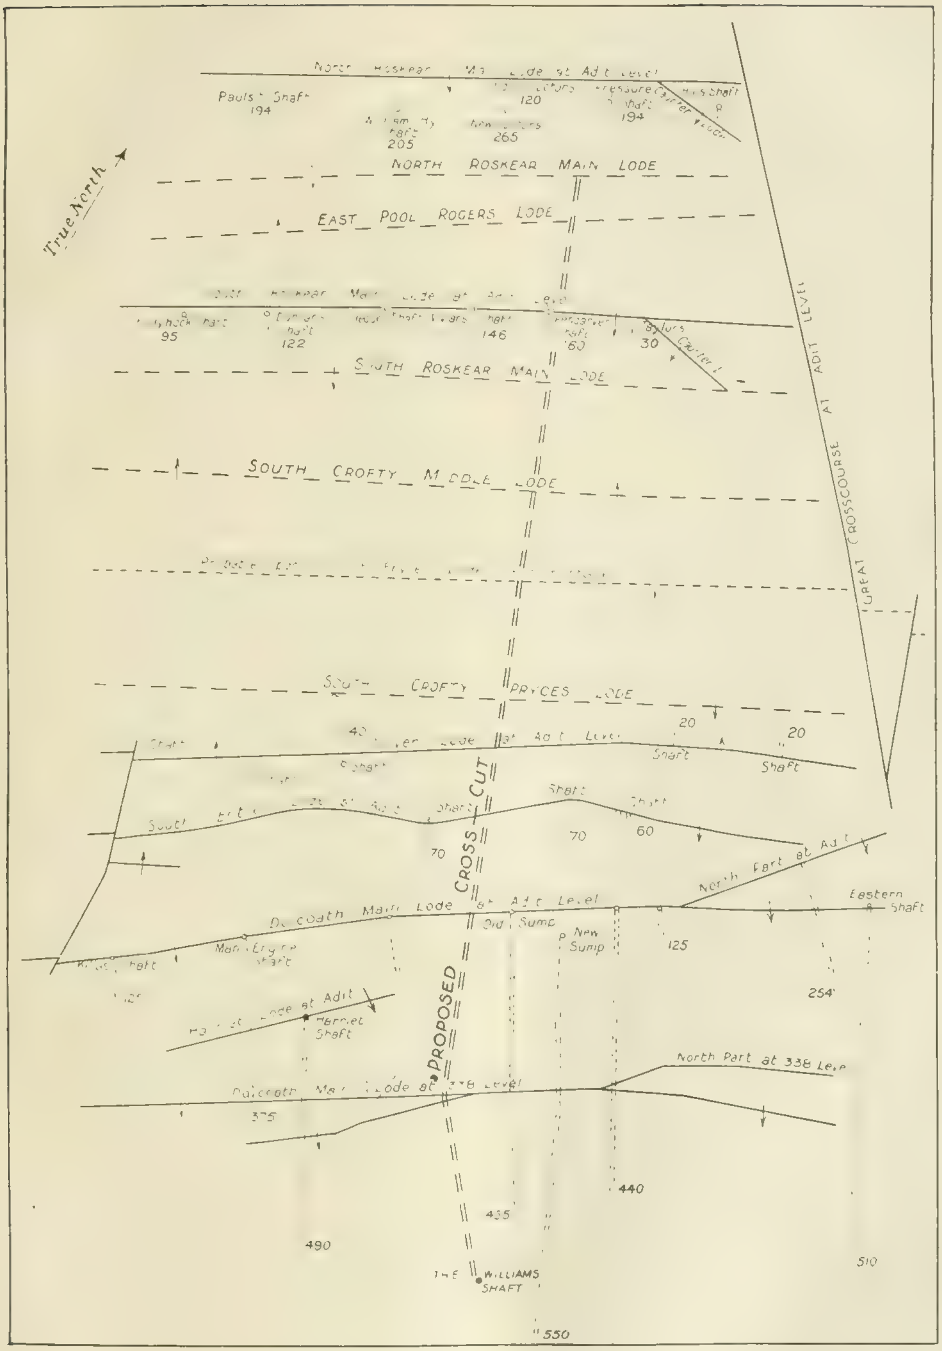
(3) Dolcoath mine produced copper to the value of £2,328,435, and subsequently in the granite tin realizing £6,842,351 by working to a depth of 550 fm. from surface. The South and North Roskears produced copper to the value of £1,024,623 and in the latter working tin to the value of £121,171. The adjoining properties, the Setons, also produced copper to the value of more than £1,125,000 and tin to the value of over £500,000. The foregoing figures in themselves without giving a detailed history of the working of these properties show this area to be highly mineralized, and it must be remembered that the above returns were made mainly when copper and tin were at a very low price.

(4) The geological conditions in these northern areas being similar to those at Dolcoath, the fact that there was a distinct change in the country rock in the bottom of the Roskears at the 300 fm. level, and that these mines at the time of their suspension became tin producers, coupled with the relative proportions of tin and copper produced (particularly at Dolcoath) on its main series of lodes provide prima facie evidence that the expectations for discovering tin by the proposed cross-cut in the granite are well founded.

(5) The recent discoveries in South Crofty, which adjoins the eastern portion of this mine, and the East Pool and Agar mines (particu-



TRANSVERSE SECTION FROM DOLCOATH TO THE ROSKEAR MINES.
The figures represent depths in fathoms below Adit Level.



Plan of Dolcoath and Roskear Lodes

Lodes at Adit Level marked in full lines; lodes at depth of proposed Cross-cut in broken lines.

larly the phenomenally rich Rogers lode) have undoubtedly demonstrated that the northern series of lodes are highly productive for tin in the granite and are distinctly confirmatory of the view held that the group of unexplored north lodes will become, by development in the granite, tin producers and on a considerable scale; moreover, it may be said that there is a general concurrence of opinion among mining men, supported by eminent geologists, in this anticipation.

(6) Dolcoath and the Roskears are divided from the eastern group of mines, that is, South Crofty, Tincroft, and East Pool and Agar by the great cross-course, and all the mines bounding this to the west have been very large producers of copper and tin; and it may be said that the eastern mines have been very successfully worked for a great mumber of years in the granite.

(7) The 338 fm. level from which the cross-cut would be driven has been chosen because, among other reasons, it will intersect the lodes above referred to and give high backs, and at the most favourable point below the line of the killas-granite contact, so that it seems highly probable that large bodies of ore will be available for working before the cross-cut reaches the Roskear mines.

(8) The Williams shaft is a very valuable asset in this scheme of development, as it is of ample capacity for a large output, for such pumping plant and mechanical haulage as may be necessary, and is equipped with a first-class winding-engine and general mechanical and electrical appliances, providing most excellent opportunities for the concentration and rapid progression of all operations. There is no engineering difficulty in returning through this shaft the ores from the lodes that will be cut by the proposed cross-cut. The use of the Williams shaft will render it unnecessary to sink a new shaft on the northern properties, at all events for a long time ahead, if at all.

To carry out this projected work will entail an estimated expenditure of £120,000, in which estimate is included the provision for a pumping plant of ample capacity to meet the probable requirements by utilizing the pumps removed from the bottom of the Williams shaft, and for preliminary development in the lodes to be intersected by the cross-cut.

Extracts from Bewick, Moreing & Co.'s Report.

We have examined the scheme as drafted by Mr. R. Arthur Thomas, covering the exploration and working of the northern ground, including the North and South Roskear and other lode channels, as well as the probable continuation of the Rogers and other northern lodes now being worked or explored in the eastern end of the Camborne-Redruth belt. The prospects of this scheme, its feasibility, the time necessary for its completion, and the capital required are factors of importance.

We have, for several years, given close attention to the geological features of this field relating to its ore-bodies, and have prepared very complete plans and sections covering the area from Dolcoath on the west to Tolgus on the east. From these we have made the plan and section accompanying this report, in which the various known lode channels and probable continuations of lode channels are shown diagrammatically, the former by continuous heavy lines and the latter dotted. These may be divided into two groups, the one of large, well-defined productive ore channels, the other of minor channels which may develop satisfactorily in the granite. There is also the further possibility of locating unknown lodes which do not appear at the surface.

The first group includes the following lode channels, taken in the order in which they will probably be met by the proposed cross-cut: (1)—Price's; (2)—Crofty Middle; (3)—South Roskear; (4)—Rogers; (5)—North Roskear.

The second group, which for the present seems to be of minor importance, includes among others the following: (1)—Dolcoath South Entral and other lodes worked to the north of the Dolcoath main lode; (2)—Minor lodes which may continue west from South Crofty; (3)—Sundry minor lodes, formerly worked in the Roskear mines.

It has been clearly established that the Great Cross-course on the eastern boundary of Dolcoath does not cut off the known eastern lode channels, but merely displaces them to the north in the western ground, and it is therefore a reasonable inference that any strong eastern lode channel which lives to the cross-course is likely to continue west of it. Quite apart from that, however, this scheme finds justification by reason of the known lode channels in the western ground, which in the past have been so productive in copper, and have not entered the zone which experience and investigation indicate as likely to be more productive in tin. Reviewing the figures available on the Camborne-Redruth district up to the year 1919, it stands out very significantly that the leading tin producers are those mines which in the early days produced much copper, and then sank to greater depth, penetrating the granite. The

following tabulation of output of tin and copper at Dolcoath, East Pool, South and North Roskear points to the prospects of the two latter as tin producers in the granite:

	Copper Ore	Black Tin	Depth of Granite	Deepest Working
	£	£	Fm.	Fm.
Dolcoath	2,328,435	6,785,998	125 to 200	550
East Pool and Agar	457,322	2,700,736	135 to 212	340
South Roskear	217,993	15,160	? 255	170
North Roskear	806,630	106,011	? 280	280

The remarkable richness of the belt of country running from Dolcoath on the south to old Wheal Seton on the north is shown by the following figures giving the returns to 1919, which further emphasize the possible potentialities for tin in the ground between Dolcoath and the Setons, which so far is practically unexplored in depth:

	Copper	Tin	Total
	£	£	£
Dolcoath	2,328,435	6,785,998	9,114,433
South Roskear	217,993	15,160	233,153
North Roskear	806,630	106,001	912,631
Wheal Seton	535,286	71,664	606,950
West Seton	719,341	454,836	1,174,177
	4,607,685	7,433,669	12,041,344

The South and North Roskear mines have produced over a million pounds' worth of copper ores. Neither of them has, as yet, been explored in the granite, and both, in their deeper levels, have been tin producers. The early history of these two mines is obscure, and it is difficult to give exact figures covering their output and workings, but the information herein compiled is believed to be on the conservative side.

The South Roskear has been worked for a length of about 4,000 ft. The two main shafts (some 2,000 ft. apart) are Wheal Chance Engine Shaft (Gregory's Shaft) in the western section, 184 fm. below adit, or 214 fm. from surface, and the Pendarves Shaft in the eastern section, about 180 fm. below adit, or 210 fm. from surface. Old reports refer to six distinct lodes as having been located, but the main workings were confined to the South Roskear main lode, which, near the surface, is almost vertical, but from the adit level dips steeply to the south. The greater portion of the large output of copper was obtained from the adit down to the 150 fm. level, and tin began to appear in quantity at the 112 fm. level at Dunkins Shaft. The eastern workings are not connected with the western below the 80 fm. level, and the water in the former was handled by flat rods worked by the winding engine, and then passed westward along the 80 fm. level to the Wheal Chance Engine Shaft, where it was pumped by a 70 in. engine. The maximum quantity was reported as 156 g.p.m., and it was considered that the 70 in. engine was in 1876 ample for the requirements then and in the future. The mine closed down in 1881, the contributing causes being as follows: the large copper bodies were largely exhausted and the price of that metal was seriously declining; development was not sufficiently far ahead to open up the deeper tin ground, and the price of tin had declined so seriously as to discourage any attempt to go deeper.

The North Roskear Sett was over a mile long and the lode was worked for a length of over 4,000 ft., the chief workings being on the North Roskear main lode. The two main shafts (some 1,700 ft. apart) were the New Doctor's Shaft on the east, 270 fm. below adit or 300 fm. below surface, and Pearce's Shaft on the western end, 220 fm. from adit or 250 fm. from surface. Paull's Shaft, Pressure Shaft, and Prince William Henry Shaft were also sunk, all over 200 fm., so that the mine was opened up by five deep shafts as well as several to the region of 100 fathoms. Latterly the workings were confined chiefly to Pearce's and New Doctor's shafts. In 1871 Captain Josiah Thomas advocated the sinking of the latter shaft to cut the granite, which he considered was at no great depth below the bottom workings, and there he expected that a lasting and profitable tin mine would be opened up. Here, however, as in the case of the South Roskear, adverse influences became so felt that the mine was closed down. The large copper stopes had become exhausted, the prices of tin and copper seriously declined, and, although in this case the tin zone had been entered, particularly in the deeper workings at New Doctor's Shaft, still the development in that zone was quite insufficient to open up sufficient tin reserves, and therefore in 1874 operations ceased. It is worthy of note that in the bottom portion of the shaft a distinct change was reported in the nature of the country, felspar, quartz, and much mica appearing.

Having outlined the results of the operations on the two lode channels, which have been worked, those which may be expected to continue through the country to be explored by the proposed cross-cut are now referred to in the order in which they are likely to be met with in cross-cutting.

Pryce's lode channel lives from East Pool through Tincroft and well to the west in Crofty, but so far has not been worked up to the Great Cross-course. On account of its strength and persistence it seems probable that it will live in the western ground. It has produced large

quantities of copper and tin in the above-mentioned mine. In Tincroft it has, until recently, been responsible for more than half the returns, and was worked for a length of 2,400 ft.; it is considered there that it will make junction with the South lode at 257 fm. with good prospects of enrichment.

Crofty middle lode is the continuation of the North Tincroft lode after being thrown northward by Pryce's lode, and has been very extensively worked in South Crofty. Like Pryce's it has not been driven west to the Great Cross-course, there being apparently a poor zone affecting all lodes to the immediate east of the cross course. Considering, however, the great richness of the Dolcoath and the Roskears on the west, these lodes may improve in tin contents in that zone. The North Entral lode of Dolcoath, which coincides with the North Tincroft lode, was intersected at the 80 fm. level, close to the northern boundary, and after being faulted by Pryce's lode was cut by the 146 fm. cross-cut south from South Roskear in the killas.

The Rogers lode, which in East Pool has been opened up in the granite with such excellent results, was of little account in the killas. To the west it meets Reeves lode (the Great Caunter), and is faulted by it in the eastern section of South Crofty. There it is thrown to the north, its continuation being known as the Longclose lode. Unfortunately the 245 fm. bore-hole in the western section of South Crofty (east of the cross course) entered the killas before cutting the lode channel and was consequently too shallow to enter the tin zone. This lode dips to the north, whereas the South and North Roskear lodes both dip to the south, and its continuation will probably be, as shown in the accompanying section, in the neighbourhood of the South Roskear lode channel, and at the depth of the cross-cut may be expected some distance to the north of the South Roskear main lode.

The following table gives the approximate distance at which the above lode channels are likely to be cut, these being determined on the normal dips and strikes, any deviation from which will correspondingly affect the positions:

LENGTH OF CROSS-CUT.

From Williams Shaft to South Entral Lode Channel about	1,300 ft.
" " " Pryce's " " "	2,400 ft.
" " " Crofty Middle " " "	3,200 ft.
" " " South Roskear " " "	3,600 ft.
" " " Rogers " " "	4,[illegible]00 ft.
" " " North Roskear " " "	4,500 ft.

The line of section on which the above measurements are made runs from Williams Shaft to a point between New Doctor's Shaft and Pressure Shaft at North Roskear.

The depth of the granite slope is known in South Crofty and New Cook's Kitchen setts, and in North Crofty (by bore-holes), and in Dolcoath the granite has been located by the 190 fm. north cross-cut, and the bore-hole from its northern end, which are both in granite, covering together a distance of 1,430 ft. north of the main lode. The position has also been determined on the main lode. On the other hand, in South Roskear the 146 fm. south cross-cut was extended nearly 300 ft. south (on the section line) and was in killas. Therefore the surface of the granite is very closely determined as lying between the end of the northern cross-cut, at the 190 fm. level from Dolcoath, and the end of the southern cross-cut from the 146 fm. level from South Roskear. South-dipping lodes generally throw up the granite floor, and north-dipping lodes depress it. It appears that in the present case the former tendency will be the more marked.

Variations in the dip of the granite surface may occur, and for that and other reasons the proposed cross-cut should be driven at a depth considerably below the granite floor, which is considered to be very close below the 255 fm. level at North Roskear. The depth proposed, 338 fm. below adit at Williams Shaft, provides reasonably for this contingency and allows for good backs on the various lode channels intersected. On the normal dip of the granite surface and lodes, as shown in the accompanying section, there would be on the South Roskear lode about 500 ft. of backs, and on the North Roskear about 300 ft. of backs.

On both the South and North Roskear lodes there were very considerable lengths of rich copper lodes, and the best line for the cross-cut would be underneath the richest portions of the old copper workings, which allows considerable latitude in location. The position chosen in the neighbourhood of Doctor's Shaft locates the cross-cut favourably for exploration of the probable tin zone in the different lode channels. The cross-cut would therefore explore the ground from Williams Shaft, Dolcoath, to Doctor's Shaft at North Roskear, following practically a straight line connecting these two points with, however, a slight deviation to allow the cross-cut to avoid old workings on the Dolcoath South and Main lodes, which should be cut in a distance of about 700 ft. from Williams Shaft. The location of this point is of such importance as to warrant, before commencing the cross-cut, a check survey from Williams Shaft to the workings to the near east of Harriett Shaft.

GOLD MINING IN CHILE.

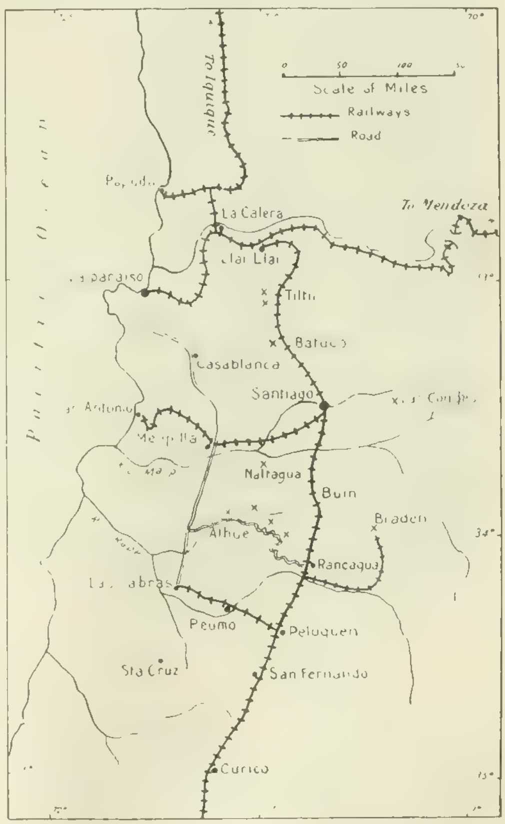
By LAURENCE PITBLADO, M.Inst.M.M.

The Author writes of a neglected industry, the mining of low-grade deposits, which can be done under most favourable climatic and economic conditions.

HOLDING the third place among gold-producing countries up to the 18th century, Chile has now descended to practically the lowest on the list. Judging by its status as a metal-producing country, one would naturally have expected this condition of things to be reversed. It cannot be said that the Mining Laws of the country are against the industry, as they are the most simple and indulgent known to me, giving a right to mine over every hectare of ground taken up (about 2·43 acres), not necessarily in square blocks, but as rectangular as the nature of the ground demands, or the surveyor requires, along the run of the vein, for the small Government tax of 10 pesos (say 10s.) per annum.

No labour conditions are involved, so naturally this allows of a tremendous amount of "shepherding" of claims. This militates against the due working of any likely mines by foreign companies, as the owners generally demand such a price as to frighten all investigators away. This, I think, may be taken as the prime cause of decay and neglect, as no engineer is going to allow a big cash purchase price for only a hole in the ground, with no reserves blocked out, and very often no road whereby to reach the "mine." The same cry is repeated time and again in Chile that the London capitalists are too exigent and want only developed mines. This, as a matter of fact, is not the case, as nearly all the properties on offer must be approached from the undeveloped point of view. So the owner, frequently refusing quite good offers, goes on paying his "patentes" (taxes), holding his ground until death overtakes him. Then his heirs would thereafter gladly sell for half the original amount demanded, if a capitalist could be found to again take it up.

Stretching along a coast line of some 3,000 miles in length from north to south, the difference in climate ranges from tropical to glacial, and these again are varied by the immense heights to which the Cordillera rises over sea-level. The latitude of 31° between Valparaiso and Coquimbo serves very well as an imaginary boundary line, north of which the country is arid and barren, while south thereof every prospect pleases, and the land might be said to flow with milk and honey. The north suffers not only from lack of transport, but more often from lack of water, and only in rare cases does it hold out an inviting aspect to the inspecting engineer. Again, while the principal industry of the north is mining, that of the south is undoubtedly agriculture, though there are large deposits of coal and a limited mineral wealth of deposits of lower-grade ores, which are found ranging from Coquimbo along the coastal mountains, and down through the central valley to the

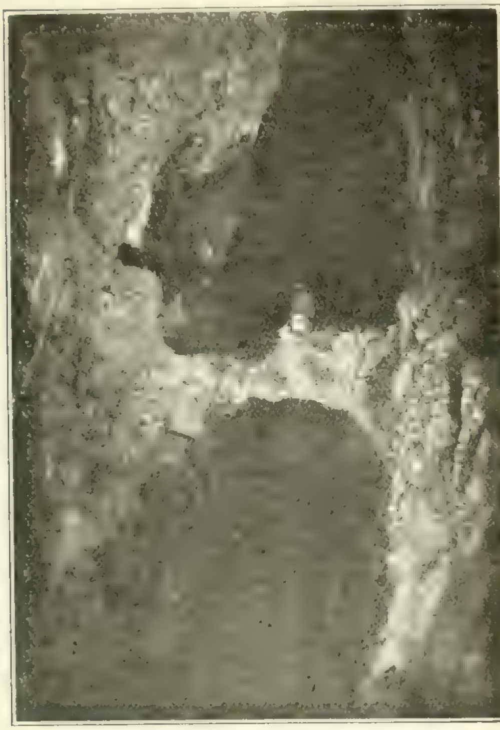


Map of part of Chile.

beach sands of the inlets and fiords of the various straits forming Chile del Sur. Occasionally the gold diggers on the beaches of Chilean Tierra del Fuego, especially after high tides, used to get fair hauls. A progressive Austrian named Popper minted all his own gold himself, in the shape of little coins weighing one gramme. I have one in my possession. On one side are

the words: El Paramo, Un Gramo, Au 864 Ag 132, and crossed miner's hammers; on the other, Tierra del Fuego, Popper, and the date 1889. El Paramo was the name of Popper's mine. The minting is very well done.

Around Tiltil, to the north of Santiago, there are large bodies, or lenses, of heavy pyritic ores carrying gold, which have been worked in a sporadic fashion. They do not lend themselves readily to any simple metallurgical treatment, and so have more or less been relegated to the "shepherded" class of mines. While they



An Old Stope at Lo Mejia

would suit a smelter well for a pyritic flux, carrying a small percentage of copper in addition to the gold, there are none in the neighbourhood, and one which used to be in blast alongside Tiltil station is now dismantled.

At a radius of about 50 miles south of Santiago, and between Rancagua and Melipilla, there are quite a number of low-grade gold-mining propositions suffering from neglect, but rejoicing in a climate that is all one could desire. Unfortunately the "haciendados" (farm owners) in this district do not like, and certainly do not encourage, the prospector to fossick around their fields and camps. If an "extranjero" to the place should take it into his head to go prospecting, then the unanswerable argument of a shot-gun is brought to bear, and the trip is quickly abandoned for fresh fields and pastures new.

On the head waters of the Alhué Creek, at an elevation of some 3,000 ft. above sea-level, the oldest and most extensively worked Minas de Oro de Alhué form a compact, self-contained group of mines. As far back as 1700 the principal lode, the Madariaga—and which to-day the natives call the mother lode of the district—was worked and was mentioned favourably as a gold-producer in the annals of the state. Their old records of yields of so many castillanos per cajon (1 cast. = 4·60 grams, and 1 cast. per cajon = 1 dwt. per ton) can still be consulted, and even to-day approximates to the new development work as a large low-grade ore deposit, easily mined in its oxidized ferruginous workings, but left severely alone whenever hard quartz had to be driven on. Apparently heating the rock and then quenching by water constituted their best means of driving in hard material, and little work was ever done on the quartz veins proper until the advent of a Chilean company about 1880.

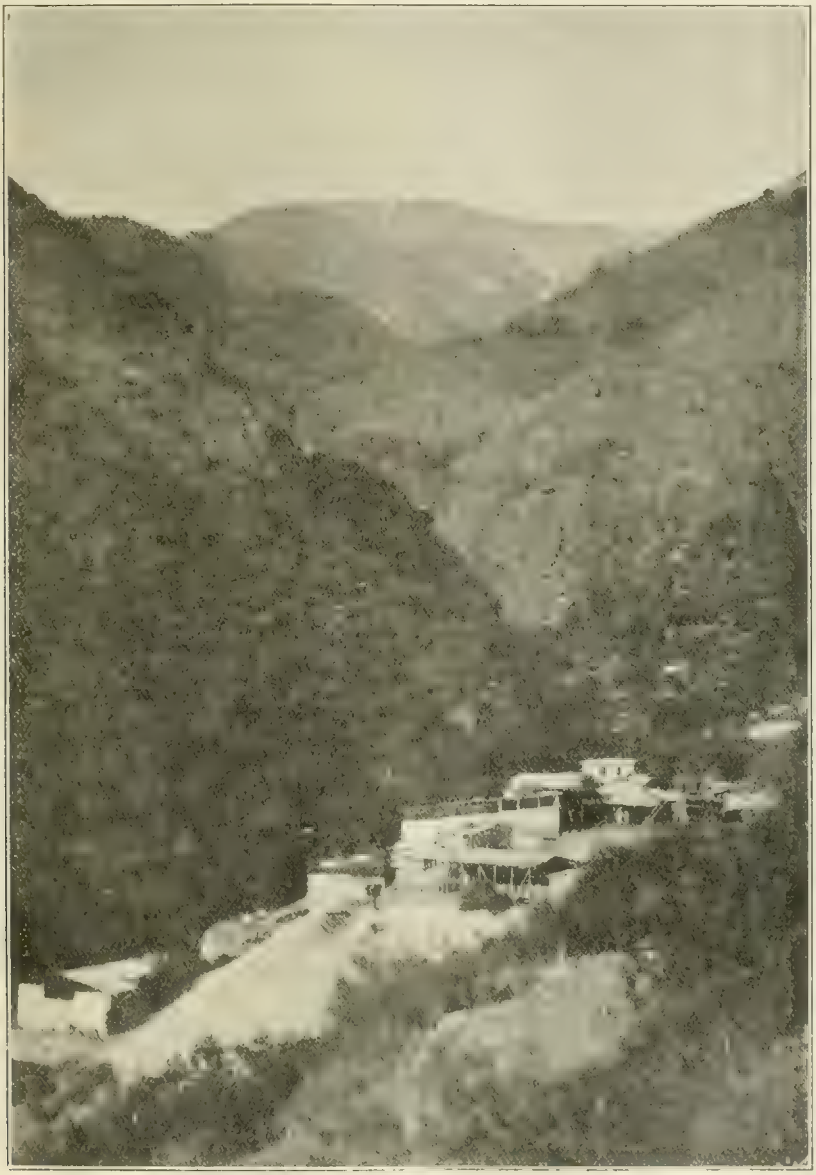
This group of claims, as now owned by the Albion Mining Company, Ltd., include the old Madariaga, Lo Mejia, Flor de Alhué, Profeta, Tribuna, etc., amounting to some 12 in all, cover an area of 105 acres. As is usual in Chilean deposits* the strike of the veins is more or less east and west, but two dip north, ranging from 80° to perpendicular, while the Madariaga and various others conform to the major rule in other districts by dipping south. If one were to generalize on the ground developed, the north-dipping veins show up rather better in average values than the south-dipping veins. The country formation is principally diorite, with strips of schists on the mountain tops 7,000 ft. over sea-level, steeply inclined away from the Alhué valley, so that none of these are visible in the claims. With the exception of one vein, all the lode walls stand well, necessitating no timbering, as is shown in the photograph of an old stope on Lo Mejia. Probably that stope to-day is as good as on the day it was opened, in spite of frequent earthquakes.

The vein matrix is mostly a hard bluish quartz, which in Lo Mejia is freely mixed with rhodonite (silicate of manganese), and when freshly broken shows up a beautiful pink colour. In Flor de Alhué, a bold outcrop on the mountain side carries large quantities of pyro-

* See the article by E. David Pope, The Mining Magazine for June, 1905.

lusite in the oxidized zone, and as may be inferred from the nature of this (according to Spurr), the values are poor until some considerable distance is driven into the ore-body.

in the veins, though where these grade into country without any cleavage wall, generally the hanging-wall side, they form a disseminated link, as it were, between barren rock and



OLD WORKS, WITH CERRO CANTILLANA BEHIND

payable vein stuft. In the case of the rhodonite vein, assays have proved that most of the values are carried in the quartz, while the gold throughout all the claims is in such a fine state of division that no free gold is visible in any stone, a point which certainly tells largely in

A like characteristic to the northern fields of Coquimbo and Atacama is noticed in the Madariaga by the presence of quantities of specular iron ore, generally valueless, which is repeated in two of the neighbouring deposits not far from here. Pyrite is found in very small quantities

favour of the company, as no finger amalgamation takes place.

Metallurgically the ores are ideal for direct treatment, crushing in cyanide solution, combined with counter-current decantation, as they do not filter well, and the consumption of cyanide only runs to about half a pound per ton. In fact, in treating the rhodonite ore alone, over 98% extraction can be obtained for a consumption of ⅓ lb. KCN per ton.

[illegible]

The widths vary from 2 ft. in the Profeta to 49 ft. in the Madariaga, but a good stoping average of the remainder may be taken as 6 ft., while over such a width assays work out about 7 dwt. per ton. When regular stoping work is in progress it is expected this width may be cut down to 4 ft., with a corresponding rise in assay-value to the half-ounce, as the centre foot of the vein carries richer values, ranging up to 27 dwt. According to the books of the previous owners, the ore milled has averaged about the first figure given, and as they only amalgamated over plates, securing an extraction of 50%, the tailings still carry 3·5 dwt.

No shaft-sinking is necessary, at least for years to come, on any of the veins, as the "backs" available from zero levels run up to 1,300 ft., so all the dormant capital involved both in shaft-sinking and winding machinery is entirely obviated.

Water throughout the district is plentiful, and on the property, as can be seen from the photograph, the country is very precipitous, so that heads up to 3,500 ft. can be obtained for power purposes. The mountain peak in the background is the highest on the coastal range, Cerro Cantillana, 7,400 ft. above sea level, and 4,000 ft. above the old works site. During the summer months, from December to April, the water flow is small, but it never runs dry, and with the head available it is expected to yield all the power necessary for an output through the mill of 200 tons per day. Working costs, as may be imagined from the foregoing description, are very low, and when the hydro-electric power plant is installed it is expected that for tonnage treated these will be far below the Rand averages of milling ore of 7 dwt. grade.

There are at least two other large properties in the district with similar characteristics, one of them being well situated for transport to and from the railway station of Rancagua, in the central valley of the country, and an important town on account of the Braden Copper Company's line branching off from here. The properties are, however, "shepherded" by their Chilean owners, and no practical work has ever been done on modern lines, so that these and many others are likely to go on lying fallow until the demands of the owners are moderated.

Climatic conditions, as has already been mentioned, are ideal. Winter, with its snows, and rains, and frosts, is as cold as at home, while the summer is more balmy and never enervating, blankets being a necessity on beds all the year round. The economic features also of the locality, provided as it is with wood, water, grass, and in the valleys all the grain and fruits that heart of man could desire, are such as are rarely met with in a mining camp.

Cooperite. — The secretary of the Zirconium Alloys Syndicate, of 64, Victoria Street, Westminster, writes to *The Times* to say that cooperite, the new cutting medium for machining metal, was tested at the Sheffield Testing Works, on December 1, with the result that at the same speed and feed the tool removed the same weight of steel per minute as the best high-speed steel, but it lasted 21 minutes 21 seconds as compared with 2 minutes 20 seconds for the other tool.

NEWS LETTERS.

TORONTO.

December 13.

METAL OUTPUT OF ONTARIO.—The Ontario Department of Mines reports that the output of the metalliferous mines, smelters, and refining works of the province for the nine months ended September 30 amounted in value to $35,920,418, as compared with $27,875,713 for the corresponding months of 1919. Production during the last two months has been curtailed to such an extent by power shortage that a proportionate increase for the last quarter of the year cannot be expected. The gold output was 424,297 oz. of the value of $8,735,768, an increase of $1,161,182, or 15%. The leading producing mines were: Hollinger $4,620,800, McIntyre $1,603,376, and Dome Mines $1,515,086, the total production of the Porcupine camp being $7,938,649. Silver production increased from 7,475,396 oz., valued at $7,898,220, to 7,831,132 oz., valued at $8,435,088. With the exception of 32,073 oz. recovered from nickel-copper refining and 71,990 oz. from gold-refining operations, the output came from Cobalt, Gowganda, and outlying areas. Nickel was produced to the amount of 7,060,078 lb. valued at $2,440,303, as compared with 7,820,866 lb. of the value of $2,732,676 during the first nine months of 1919, and exports of nickel in matte were 17,446 tons, valued at $8,723,000, as against 11,301 tons of the value of $5,424,552. Copper in matte exported amounted to 9,497 tons, value $2,659,160, as compared with 6,818 tons, valued at $1,908,936. The output of pig iron showed an increase from 30,849 tons, valued at $795,009, to 49,422 tons, valued at $1,395,048.

PORCUPINE.—The output of some of the mines is being seriously curtailed by the shortage of electric power which has continued for some time, the outlook for the winter being dependent on the continuance of open weather and sufficient rainfall to restore the level of the lakes and rivers before winter sets in. So far the weather has been unusually mild for the season, and the supply of power shows some improvement. The Hollinger Consolidated has met the difficulty by the use of an auxiliary steam plant and is steadily increasing its working forces. The company has declared a dividend of 1%, payable December 31, being the ninth to be paid this year, making a total disbursement for 1920 of $2,214,000. Production at the Dome Mines has fallen off temporarily owing to power shortage and the breaking of an underground crusher. About 700 tons of ore are being treated daily, as compared with between 900 and 1,000 tons during the first nine months of the year. This is offset by a considerable improvement in the grade of the ore treated, which is stated to average about $7 per ton, operating costs being estimated at $3·50 per ton. At the McIntyre the new vein system, lying about 400 ft. south of the No. 5 shaft, is being opened up on the 1,375 ft. level, where the vein is 20 ft. wide with high gold content. This development is regarded as of importance to the Hollinger Consolidated, as the system is believed to be a continuation of its No. 84 vein, and its persistence at an equal depth to that proved up on the McIntyre would mean a considerable increase to Hollinger's ore reserves.

KIRKLAND LAKE.—The large new mill of the Wright-Hargreaves with a capacity of 150 tons daily will be completed and ready for operation at the close of the year. The time of starting work will depend on power conditions. The mine is in condition to keep the mill continuously supplied with ore. Most of the development has been on the 400 ft. level, the ore being high in grade. Stations are being opened on the upper levels preparatory to lateral work. As the Wright-Hargreaves location extends for nearly three-quarters of a mile on the main belt of mineralization, having the Lake Shore mine on one side and the Tough Oakes on the other, it is expected to become an important producer. The Lake Shore during October treated 1,570 tons of ore, yielding $47,077, being a considerable increase over the two preceding months. The average extraction of $29·98 per ton made a new high record, and was the highest average ever established by a steady gold producer in Canada. The main shaft is now down 514 ft. The company is keeping production up to normal by the use of steam power. Thackeray Mines, Ltd., which owns 250 acres in the Kirkland Lake area in addition to several holdings elsewhere, has discontinued operations for the season and is planning for extensive development work in the spring. The Hunton-Kirkland is increasing its capital stock from $1,500,000 to $2,500,000.

COBALT.—The silver-mining industry has been hard hit by the drop in the price of silver which, combined with the shortage of power, has considerably reduced the margin of profit, resulting in the closing down of some mines and the passing of dividends by the Mining Corporation of Canada and the McKinley-Darragh. Operating costs are high, the principal item being wages, which remain at the

same figure as when silver was bringing its highest price some months ago. Labour is now plentiful and mine managers are able to pick their men, with the result that efficiency on the part of workers is showing some improvement. The miners are stimulated to increase production by the prospect of being thrown out of work should the mines close down, or of a cut in wages in case the companies resort to this alternative to bring down operating costs to a point which will enable them to continue to work at a profit. Some operators are again storing their bullion in the hope of a better market. The Nipissing during November mined ore of an estimated value of $199,219 and shipped bullion and residue from Nipissing and customs ore of an estimated net value of $232,526. The company, in addition to its regular quarterly dividend of 5%, has declared a bonus of 5% extra. The Chambers-Ferland has made an important discovery of silver at a depth of 385 ft., the deposit being 20 ft. wide and yielding assays of 28½ oz. to the ton. A winze will be put down into the underlying conglomerate where the ore-body is expected to show greater enrichment. The Mining Corporation has discontinued pumping tailings from Cobalt Lake, having stacked a sufficient tonnage to keep the mill running through the winter, thereby effecting a large saving of power. The Beaver Consolidated, which was closed down for a short time while the mill was undergoing repairs, has resumed operations.

GOWGANDA.—The Miller Lake-O'Brien, a privately owned mine which produced 708,872 oz. of silver last year, paid taxes on profits of $451,000. Its profits were exceeded only by those of the Nipissing and Kerr Lake. The Sanderson Syndicate, formed in Montreal pending the organization of a company, has taken over a group of ten claims, comprising approximately 400 acres, in the Gowganda district.

BOSTON CREEK.—At the Miller Independence systematic exploration is being carried on at the 500 ft. level, to examine laterally all the formations not penetrated by cross-cutting, and subsequently to determine the gold content at depth by diamond-drilling. A vein encountered in cross-cutting on the 500 ft. level is being driven on. Henden's Trust, Ltd., whose address is 3, London Wall Buildings, London, E.C.2., has started work on the Hughes-McElroy property, comprising nine claims about 4 miles from Boston Creek, with Frank C. Loring as consulting engineer. The Peerless has resumed operations.

VANCOUVER, B.C.

December 7.

COPPER MINING.—The British Columbia copper-mining industry has received an unpleasant set-back by the closing of the Britannia Mining & Smelting Company's concentrating plant at Howe Sound, and the stopping of the shipping of concentrate to the American Smelting & Refining Company's smelter at Tacoma. The development of the mine will be continued, but fully half of the men have been dropped from the pay-roll. Of late years the Britannia has contributed about one-third of the copper output of the province, while last year it was the only copper property to maintain its rate of production at the level of the previous year. Its output was 17,250,000 lb. of copper out of a total production of 42,500,000 lb., and it also contributed 98,600 oz. of silver and 4,200 oz. of gold to the precious metal output. Ordinarily the mine gives employment to between 600 and 700 men. At the end of last year the ore reserve was estimated at 9,000,000 tons assaying slightly in excess of 2% copper, with small values in precious metals.

Unfortunately also the Granby Consolidated has started to curtail production and has laid off 400 men, and the Consolidated Mining & Smelting, though continuing smelting operations, has stopped all new construction and laid off the men that were working on it. This means that work on the new 2,500-ton concentrator to treat the Rossland ores, the 2,500-ton concentrator to treat the Sullivan mine ore, and the new copper-rod mill has been stopped, pending a better condition of the base metal market.

The Granby, which operates the largest copper smelter in the British Empire, is in a precarious position, as is reflected by the share quotations, which at the time of writing are standing at $20. In 1913 these shares had a low record of $51 and a high record of $78¼, while at one period in 1916 they climbed to $120. Toward the close of and since the war, the company spent large sums of money in improvements, which included the purchase of coal lands, the development and equipping of a colliery, and the erection of by-product coke-ovens and other improvements at its smelter at Anyox. When the investments were made it was intended that these improvements should be paid out of earnings, but with the armistice came the slump in copper prices, and, instead of paying out of earnings, two bond issues had to be floated, amounting to a total of $4,003,300, and these draw an an-

nual interest of $209,198. Metallurgically, the colliery has not been a success. The coal gives a very high-ash coke that has produced trouble in the furnaces, necessitating additional fluxes. Added to this, the title to the coal lands purchased was not clear, and this has plunged the company into expensive litigation. The case is still before the courts; in the last trial title to the colliery was given to the Esquimalt and Nanaimo Railway, a subsidiary of the Canadian Pacific Railway. The Granby has appealed the case, and, in the meantime, in consideration of a deposit the court has allowed the Granby to continue coal-mining operations, but has limited the output. The colliery is now producing about 20,000 tons of coal monthly, a large part of which is sold. Provided that the company ultimately regains title to the coal lands, they should prove to be a good investment. During the financial year ended June 30, 1920, the company earned $1·03 per share. The total output amounted to 23,127,849 lb. of copper, 938,292 oz. of silver, and 14,616 oz. of gold. The main portion of the silver, however, was derived from Dolly Varden ore, which the Granby purchased, the ore acting as a flux to the Hidden Creek ore. The yield approximately was 31 lb. of copper per ton of ore smelted, which was an increase of some 7 lb. over the previous year's operation; the increase being due to the closing of the Phœnix mines, which were playing out and reduced the tenor of the whole.

The Anyox plant is in splendid shape; it has a capacity of 2,500 tons daily, and is capable of producing 44,000,000 lb. of copper yearly. The Granby Company is a United States owned concern and is backed by strong financial interests, and there is no doubt but that a big effort will be made to bring the company once more to the strong position that it has held in the past. There is a considerable amount of unemployment in the province, and there is no doubt but that a lower wage-scale ultimately will obtain, though the miners, who have been enjoying a high wage-rate, will resist it to the last ditch. One thing, however, is pretty certain: with its heavy bonded indebtedness the Granby Company cannot continue to operate profitably under present wage conditions with copper much below 15 cents per pound.

The Canada Copper Corporation is another victim of adverse conditions. After running its plant for rather less than two months, it closed its mine on December 9 and its mill two days later. During this time the plant was never tuned up to more than about one-third capacity. The manager states that the plant was giving complete satisfaction, but that when the price of copper dropped below 15 cents per pound operations ceased to be profitable, and the directors decided on a close-down. Some time before the plant was stopped the men were asked to accept a reduction of 50 cents per day in wages until the copper market improved. This they refused to do, with the inevitable result as recorded. The company has issued the following statement: "Owing to the low price of copper, which has been gradually dropping for the last few weeks until it has reached an alarmingly low figure, it has become necessary to close down the mine and plant at Copper Mountain and Allenby. The Canada Copper Corporation is in a position to operate at as low a figure as any other company, and if the price tends upward to such a figure as concordant with the present cost of supplies and scale of wages will allow the company to make a fair profit, operations will be resumed." It is exceedingly doubtful whether at the present cost of labour and supplies current in British Columbia any company can produce copper profitably when the price of the metal falls below 15 cents.

GOLD MINING. — At the present time, everything points to a considerable falling off in the gold production of the province during the present year. The Rossland mines, which are the principal producers of the province, have been closed for the greater part of the season. They were re-started about six weeks ago (in the beginning of October), but this to a great extent has been off-set by the closing of the Nickel Plate mine at Hedley at the beginning of November. Of late years the Nickel Plate has been producing between twenty and thirty thousand ounces of gold yearly and about $20,000 worth of arsenic. The closing of the mine has thrown more than 100 men out of work, but, as their insistent demand for wage increases has been the main factor in bringing about the closing of the mine, they have only themselves to blame. There is a large reserve of ore that will run better than nine dollars per ton in the mine. In closing the property the manager, G. P. Jones, stated that at the present cost of labour and supplies it was impossible to pay dividends and at the same time maintain the ore reserve, so the only sensible thing to do seemed to be to close the mine until conditions improved. It is probable, he stated, that the mine will be closed for not less than a year.

Placer mining has been at a standstill during the year. Early in the season there was a

shortage of water, the late frosts holding the water in the mountains. During the latter part of the season there has been a superabundance, too much, in fact, for successful operation. Several companies have announced their intention of putting dredges on the Fraser River next year. With the opening of the Pacific Great Eastern Railway into the old Cariboo district, and the consequent increased facility for the transport of machinery, there seems to be every reason why the Cariboo field should be attractive for gold dredging. Without doubt there is a good deal of gold still remaining in many of the rivers that might be profitably extracted by dredging.

CAMBORNE.

GRENVILLE.—The recent meeting of shareholders, called for the specific purpose of winding up the company, was ultimately adjourned to test the suggestion made by Mr. C. V. Thomas that the shareholders should find a sum of £7,000 on security of the assets of the company to enable the property to be nursed for six months, in the hope that by then the tin market would have improved sufficiently to re-commence operations without loss, and capital would be procurable to set the company on its legs again. The consulting engineer (Mr. Josiah Paull) very properly pointed out that meanwhile the mine was filling with water and the plant deteriorating, while the chairman stated that it would simply be courting disaster to re-start with the present ramshackle plant. New plant is estimated to cost from £150,000 to £200,000 at current prices. It is clear that no tin mine in Cornwall, being worked at any depth below adit, even producing ore of a recoverable grade of say 30 lb. black tin per ton and with tin metal at £300 per ton, will be able to show sufficiently encouraging financial results unless equipped on modern lines and managed by men of high technical knowledge and skill. Existing operating costs are unlikely to fall to any considerable extent; wages are not extravagant now, and the principal material cost, coal, is most unlikely to be substantially reduced in view of foreign markets awaiting that commodity as soon as export is permitted and satisfactory terms of payment arranged. It will certainly be folly to re-start without adequate capital; the present company might have weathered the present depression but for the fact that the money provided by the recent reconstruction was quite inadequate. Of the £27,000 raised, all but £5,000 was spent in meeting the old company's liabilities and in reconstruction expenses, and certainly the new money would not have been forthcoming had the then directors made the true position as clear as their duty demanded. However, there is nothing to be gained by criticism in that direction now, and we can only hope that local shareholders, who benefit more largely than outsiders, will have the courage to back their faith and opinions so as to give this fine old mine a further chance.

GEEVOR.—On December 18, 14 days' notice was given to all employees to terminate their engagements, owing to the fact that the mine, under present circumstances, cannot be operated without loss. It is stated in the notice to the employees that increased returns to meet the serious fall in the price of tin cannot be looked for until the new "Victory" shaft has been sunk to a level permitting of the hauling of sufficient stuff to allow the battery to be kept going at full capacity. It seems rather a pity that capital should have been locked up in the enlarged mill so long in advance of mine development, but doubtless the chief responsibility rests with the late manager. Geevor is one of the few mines working to a large extent above adit, and water troubles are not the usual nightmare in this case. We believe that under existing circumstances suspension is undoubtedly the right policy, and we should still express that opinion even if sufficient ore were available for keeping the enlarged mill working to full capacity, for we cannot believe that, with black tin at its present price, any Cornish mine producing only that commodity, can be operated except at a very heavy loss. We recognize that certain standing charges must continue even with operations suspended, but they must be out of all proper proportion in this case if they are not less than the operating loss. Moreover, the reserves would be being depleted with no benefit to the shareholders if working was continued. Presumably the sinking and equipment of Victory shaft will be continued in readiness for the time when stoping operations can be resumed, and this will provide employment for a limited number of men.

LEVANT.—The employees at this adjoining mine have also been given notice, but the situation here is not the same, for the pumps must be kept going unless the mine is to be allowed to fill with water. As the deeper workings are extensive, and as the best prospects, in the opinion of some engineers at any rate, lie in the extension seaward of these workings, it is to be hoped that it will not be necessary to abandon them. The incoming water at Levant is, comparatively speaking, light, and

it would be a thousand pities to have to stop the pumps. Seeing that £60,000 new capital was provided only about a year ago and that no money has yet apparently been spent in sinking the new projected main shaft, the financial position ought not to be such as to necessitate this course, unless indeed the mine has been worked at a heavy loss during the year. Working costs at this mine have for years been abnormally high owing to local circumstances, and always will be until a suitable shaft has been sunk for the proper exploitation of the lower workings.

GIEW.—As further evidence of the desire of the miners themselves to assist the companies to tide over this time of depression, at this mine the men have agreed to hand back to the company the sum of £1 per month per man until the price of tin metal again reaches £260 per ton. This spirit of good will and co-operation is to be commended, and is a heartening sign that in some cases, at any rate, given confidence in the management, the workers are willing to make sacrifices to keep the mines in operation.

TINCROFT. — At this mine, it will be recalled, the employees agreed some time since to contribute £200 per month to assist in meeting the losses being incurred, and recently they adopted and submitted the following gratifying resolution to the directors:

"We convey to the board of directors our sincere gratitude for the splendid and ready response made to our representations for the continuation of working operations during the present period of depression. We fully realize the difficulties you are up against, with the low price of tin now prevailing. It makes matters more difficult, but we have every confidence that our arsenic returns will more than compensate for the drop in price of tin. We can assure you, gentlemen, our very best efforts are being made to obtain the best results, and hope you will find it possible to continue operations during the winter months. Then, with the prospects of trade becoming normal, we may expect much better prices and prosperity for the mining industry."

It is regrettable that the directors have, after all, had to issue notices to suspend operations on January 15. The employees, who number some 200, will now have to draw on the unemployment dole of the Government, whereas if the sum so payable was handed over to the company, operations could be continued. It is hardly to be expected that the Government would adopt any such common-sense policy, although the cost to them would be the same, so it looks as if the end of Tincroft is in sight.

SOUTH CROFTY.—It is satisfactory to learn that the development of what is now termed the No. 2 North lode at the 290 fm. level has proved to average rather over 30 lb. of black tin per ton for the whole length of the drive. This lode has also been intersected at the 260 fm. level north of Robinson's shaft, its value there being 33 lb. black tin over a width of 5 ft.

TEHIDY MINERALS, LTD.—Owing to unexpected difficulties which have arisen in connection with the settlement of the account between the company and the vendors of the Basset Estate, it was found impossible to prepare and present to the shareholders at the recent meeting a statement of account as from the inauguration of the company, and so the meeting was adjourned. However, the report prepared by the general managers, Messrs. Bewick, Moreing & Co., and the statements made at the meeting give a good idea of the activities to date. The first work undertaken by the engineering staff and Dr. Maclaren was the geological examination of the unexplored tin areas in the Camborne-Redruth district. Surveys of the different mines were co-ordinated, a work of no little difficulty, and one general plan of the area and geological plans and sections were prepared showing the exploratory work necessary for the location of the tin-bearing lodes in the hitherto unexplored granite zone north of the present operating mines. The conclusions arrived at by the engineers from this work are stated to warrant the belief that this zone will prove to be a large tin producer when capital is available to finance the necessary development work. The driving of the Tolgus tunnel and the proposed exploratory cross-cut from Dolcoath to the Roskears will prove whether these prognostications are correct, but most certainly the evidence collected justifies up to the hilt these proposed developments.

A preliminary examination has been made of the iron-ore deposits in the Roche, Lanivet, and Withiel parishes, which shows that there are several long lines of lode of reasonable width, carrying shoots of good-grade iron ore which could easily be developed if a market was available for the product. These deposits were worked to a considerable extent before the more cheaply-mined Spanish ores displaced them from the market. Unless a tariff is put on imported iron ores, which is most unlikely, we see no prospect of these deposits ever being tackled.

The most promising, from an early revenue-

producing point of view, of the company's extensive mineral areas appears to be the china-clay deposits in the Bodmin district. In the Temple (South Bodmin) district there are altogether fifteen probable and possible china-clay areas, seven of which are considered by the engineers to be of first-class importance. Until they have been completely explored, their extent and commercial value cannot, of course, be determined, and attention is now being given to the preliminary work relating to the development of one section of these. Already the important question of transport has been successfully tackled by satisfactorily arranging the easements for the necessary pipe-lines. As has already been reported in these columns, the company has acquired an interest in the Cornish Kaolin Co., Ltd., owning and operating china-clay properties in the Bodmin district, and that company has acquired from Tehidy Minerals, Ltd., an adjoining area, which is being paid for in shares.

The policy of the company, in fully investigating its properties before commencing definite operations is thoroughly sound, although to the shareholder, anxious to get a return on his money, it seems slow business. In Cornwall, in the past, much capital has been wasted because of the absence of preliminary investigation work. The general managers of the company appear to be thoroughly satisfied with the result of their investigations, and we trust that, as soon as the general financial position improves, capital will be forthcoming to start operations which will lead, in the words of Captain A. H. Moreing, "to an era of prosperity such as seldom has been equalled and never excelled by any company or body of persons in Cornwall before." These are brave words and perhaps somewhat on the optimistic side, but they are evidence of the confidence of the general managers in the company's future.

CALLOOSE.—The consideration by the Court of the petition for the winding-up of this company was adjourned pending a meeting of shareholders with a view to ascertaining their wishes, and, if it was decided to continue, then on what terms. This meeting was subsequently held, when by a large majority it was decided not to wind up, but as no scheme was presented, a further meeting will consequently have to be held. In a circular issued by the vendor (Mr. A. F. Calvert) of the company's properties, he claims that his opposition to winding up is in the general interests of the shareholders, and that, according to local opinion, the properties will prove profitable. Shareholders disposed to believe that these properties are as valuable as claimed by the vendor will do well to ask for the names and status of the engineers who have expressed that opinion and to call for the publication of their reports, so that they may be examined.

EAST POOL & AGAR.—Since my last letter, yet another lode has been intersected in the cross-cut to the Rogers lode at the 252 fm. level. This lode is believed to be Branwell's lode, and at the point of intersection it shows excellent values. This is the third lode met with in this cross-cut, each of which has assayed well above the milling average. It is evidence of the highly mineralized nature of this part of the mine, and, once the price of tin advances, should enable handsome profits to once again be earned by this company. To judge from the monthly sales and known operating costs, the mine must, at present, be working at a substantial loss, but the splendid development results of the past few months indicate a rosy future once the price of tin improves.

KIT-HILL & HINGSTON DOWN MINES.—The Duchy of Cornwall has abandoned all work at these mines, and the machinery and plant was recently put up to auction. The Duchy was influenced to start work on these properties in 1916 by the then national shortage of wolfram, but difficulties in securing the necessary plant delayed the commencement of milling operations on any scale until early in 1919, by which time wolfram was practically unsaleable. The capital expended on this enterprise amounted to over £75,000, and we fear that this unfortunate experience will discourage the Duchy from undertaking any further exploitation of its many mineral properties in the West of England.

DOLCOATH. — The accounts for the six months ended June 30, 1920, have at last been issued, and a loss is shown of £11,825. This is somewhat less than was perhaps expected, but, from the financial position disclosed by the balance sheet, it is clear that, without further capital, operations could not be continued for long. The tonnage of ore treated for this period was 30,052 tons, from which was produced 338·5 tons of black tin (average recovery 25 lb.) which realized £70,752. The total receipts figure at 49s. 8d., the working costs at 57s. 2d., and the loss at 7s. 6d. per ton milled.

Accompanying the directors' report was the report by Messrs. Bewick, Moreing & Co. on the Roskear scheme. This is given in full in another part of this issue, so that it need only be said here that they are very favourably im-

pressed with the possibilities of the proposed exploratory cross-cut from the Williams shaft to test the granite area between that shaft and the Roskears, the cost of which is approximately estimated at £120,000. To raise this sum, it is proposed to form a new company with a capital of £350,000 (the same capital as the existing company), and to issue one £1 share, 10s. paid, in exchange for each share held in the old company. If fully subscribed, this would realize a sum of £175,000, which would allow for the registration costs of the new company, the payment of outstanding liabilities, and doubtless leave still a margin beyond the sum estimated by the engineers for the proposed exploratory work. The money will be called up by small instalments spread over probably eighteen months, and it may be surely expected that local people will take up all shares not subscribed for by the present shareholders, as the district is so largely dependent on the success of this undertaking. The debenture debt of £75,000 will be continued, and Messrs. H. Montagu Rogers and C. A. Moreing will probably join the board of the new company. The scheme has been very well received, the only criticism we have heard being whether the work can be carried out for the sum estimated. In these times, close estimating is out of the question, and we doubt whether any one has better knowledge than Mr. R. Arthur Thomas and Messrs. Bewick, Moreing & Co. (who substantially agree as to the cost) on which to form a reliable judgment.

NORTH OF ENGLAND.

Lead and Zinc Mining in 1920.—Lead and zinc mining in 1920 has been a long and hopeless struggle against adverse circumstances. The price of pig lead has been subject to violent fluctuations, the mean February average being £50. 12s. 9d. against £21. 10s. on December 16, and spelter, which in February last was £62. 3s. 6d., is now (December 23) £22. 10s. The market for galena has been difficult, as the smelters could not anticipate what additional charges might be placed upon them, and they have been reluctant to enter into forward contracts for ores. Several mines even found difficulty in selling spot lots, except at exceedingly low prices, and a few stocked production in the hope of a more satisfactory price in relation to the price of pig lead. The mine-owner has, however, to accept the position that any additional cost incurred by the smelter has to be added to the returning charge, and every rise in coal or labour has been passed on to the producer of galena. The returning charge was in pre-war days about 40s. to 45s. per ton for high-grade ores, but lately smelters have asked as much as £10. 10s. 0d. f.o.r. I think, however, that galena might be sold at about £7 returning charge, as tentative offers have been received for shipment below this figure.

Certain old contracts are still in force at a much lower returning charge, and the smelters have made no effort to denounce them. We miners have hitherto been always fairly treated by the lead smelters. Taking a returning charge of £7, galena 80% Pb, silver 8 oz., the price in February was £34. 10s. 0d.; in December the same ore was worth £9. 16s. 0d., a drop that is rather startling.

With regard to blende, there is really no market. All the home zinc smelters have now closed down, except Seaton Carew, where there is a small production, and the only real outlet is the Continent. I can give no idea of the price obtainable now, but when spelter was about £48 two fairly large parcels were shipped to Antwerp at a figure that gave the mines about £9 net. With spelter at the present level there can be no resumption of production, the Swansea works finding that £52 is the minimum figure at which they can cover costs. It has been suggested, in influential quarters, that the Government should supply blende at a nominal price as long as large stocks are available, and thus galvanize the corpse into temporary vitality.

The only blende producers who have a certain and satisfactory market are the Australians, and the chairman of the Sulphide Corporation stated on December 22: "For our production of zinc concentrates a satisfactory market is assured through the contract made by the Zinc Producers' Association with the British Government, which runs until 1929." Our Mine Owners' Association has constantly pressed for the inclusion of the home mines in this contract. Verbal promises made during the war have, however, been repudiated, although the whole facts were laid before Sir Robert Horne in June. The President of the Board of Trade did not hurriedly reject our claims, as an answer was only extracted late in December. This was to the effect that the Government refused to place us upon the terms granted to the Colonies. The stock of zinc concentrates purchased is already over 500,000 tons. This is lying at port in Australia, and the current output will be acquired under the contract until 1929. Mr. Bridgeman also states that he cannot recommend the inclusion of our

home mines in the Key Industries Bill. The logic of these eminent gentlemen is unimpeachable. They are buying blende abroad, and by destroying the home producer until 1929 they have at least one competitor disposed of. The differentiation against the home producer is, I hope, unique in the history of muddle and incompetence that has characterized the mining "policy" of the present administration. The effect has been to kill the industry, and the end of 1920 leaves this country without a single blende mine in operation, and a Government buying enormous quantities of blende at a "satisfactory" price, which it is trying to dispose of to the continental smelters.

I do not assert that the Government's hostile policy is the only cause of the present disastrous position. It is perhaps the most important factor, but the costs of material and labour have been steadily increasing during the year. I give a few comparisons, partly from market quotations, and partly from actual invoices.

	1919. per ton.	1920. per ton.
Slack Coal	33s.	43s. 3d.
Anthracite for engines	54s. 1d.	72s. 6d.
Sieving (standard clothing)	£15	£19. 13s. 9d.
Cement	£4 19s. 8d.	£6. 5s.
Gelignite 50%	£140.	£160.
W. Coast Hematite Iron	£10. 4s.	£15. 15s.
Round bars	£21. 15s.	£30. 10s.
Rails	£16. 12s. 6d.	£26.
Bolts and nuts	£45.	£57. 10s.

At one mine (the conditions in the two years being identical) the cost of coal in 1914 was £5,700, and in 1920 £15,000. Replacements have been bought at ransom prices; for instance, trommel cast iron centres 1914, 12s.; 1920, 80s. I need not labour the point, but the coal-miner has in fact obtained his specially favoured position at the cost of the rest of the community.

As to labour, there has been a general rise of 6s. per week, awarded by the Industrial Court, under the ruthless pressure of the Unions, and further claims have been recently advanced. The mines have, however, closed down in the meantime, a quite convincing answer to further claims.

I have heard in several instances of an improved standard of effort among the men, and in some cases the level of output is as high as pre-war. This is all to the good; nevertheless it will have to be realized that the wages in country places cannot be gauged by the standard in industrial centres. A very considerable level of comfort can be maintained with a much lower scale of wages in isolated districts.

I am not familiar with all mining areas, but I think it would be safe to say that no mines are covering the cost of production, and with those still in operation, the object is to see if the present crisis can be tided over.

In Cumberland, Greenside is still producing galena, but the company has gone into liquidation, and is merely engaged in crushing its large stocks of crude ore. This important mine will sell its plant some time next year, and permanently close down. Threlkeld mine, worked by adit level, has suspended production, but the owners are keeping on the men for a few months on the development of the large area of "payable" lode that has recently been laid open. Brundholme mine has no production yet, but is arranging with the Threlkeld lessees to follow a nice-looking lode into their area. Thornthwaite has quite definitely closed down for the present, about 10 men, including the staff, being retained to keep the pumps in operation and the mine in working order. Force Crag is stopped except for a few men trying a barytes deposit.

Further east in the Alston-Nenthead district, the Vieille Montagne Zinc Co. has a few men working at Nentsbury, where there is quite a nice lead deposit, but the large concentration plant is idle, and I very much doubt if milling will be resumed there. Across the Pennines, Weardale is still running with an output of over 200 tons of galena per month, but I am pretty certain that heavy losses must be now incurred with pig lead at £21. 10s. The wages in this area are the highest in the industry. Despite this fact, the 6s. advance was awarded against this company, bringing up wages to an average of 25s.–30s. per week beyond those of, say, Wales. At Lord Allendale's mines there are some encouraging developments, but I hear that they may be shortly closed down. The output is not important at present.

Taking the Scottish area, Tyndrum is practically standing, but with fair prices I believe this mine may become an important producer. At the Newton Stewart mines production has been suspended. The important Scottish mines are, of course, Leadhills and Wanlockhead. Both are looking well underground, and with fair prices would be a permanent source of supplies. They both have deep shafts and heavy pumping charges. At the moment they are in operation, but with the heavy losses now being incurred their stoppage may be anticipated. This would be a disaster to the district, as the whole population depends upon the mines. If the pumps are stopped the cost of reopening would be enormous, but the shareholders may well object to spending £20,000, at each mine,

in pumping charges for a year, with no certainty of profit at the end of this period.

In Wales, East Halkyn has now definitely closed down, and there are rumours that the plant is to be sold. The pumping charges here are very heavy indeed. The only other mine in active operation is the famous Halkyn mine, and matters have now reached an acute crisis; by the time this appears, operations will probably have ceased. The future of this district absolutely depends upon the successful prosecution of the deep drainage tunnel, which has been driven a long way already, but work was suspended in August, 1919, and so far it has been impossible to devise any scheme that would satisfy the claims of the various interested parties. The Government advanced large sums during the war, but additional capital is required to complete the work. A conference was held under the chairmanship of Sir Charles Stewart, but proved abortive. I do trust that further efforts may be made, as the scheme is absolutely sound in its conception. It would unwater the following mines in the order named: New North Halkyn, Halkyn, Mount Halkyn, Bryngwiog, East Halkyn, North Hendre, South Halkyn, Llynpandy, Pantymwyn; giving a further depth of 200 ft. free of water to most of them, but in one case at least 350 ft. To show the importance of the tunnel, East Halkyn sunk its shaft about 90 ft. below the old tunnel, and had to pump a steady flow of 4,000 gallons per minute to keep the workings clear of water; yet, despite the richness of the deposit, the cost of pumping has now rendered it impossible to work the mine. The mines mentioned are, more or less, equipped with concentration plant. To an outsider it is difficult to believe that a comprehensive scheme cannot be devised by which the royalty owners, the Tunnel Co., the Government, and the mine-owners would mutually benefit.

In the Llanidloes district, the Van and neighbouring mines are idle, through the usual causes, and the new equipments erected are so far wasted. Esgairmwyn mine has stopped, but a development policy is under consideration by the owners. The Lisburne Syndicate at Frongoch and Glogfawr has erected a large plant, but work is now suspended.

In the Shropshire district practically the whole mineral area is in the hands of the Shropshire Mines, Ltd., and Lieut.-Col. J. V. Ramsden is conducting large operations there. The output of galena up to the present has been very small, but the potentialities of the district are enormous. There is here a large drainage tunnel called the Leigh Level, and the company is driving this right under the group of mines, in order to unwater the whole area. The scheme is being carried out on broad lines and with the most modern appliances, and should eventually prove a source of great mineral wealth. It is intended to sink the Bog shaft a further 300 ft. In the meantime the company has concentrated its efforts on the production of barytes, which happily is still saleable. The output of barytes during 1920 was 8,300 tons. The present number of men employed on development work and the production of barytes is about 300.

I have no further news of the Mill Close mine, Derbyshire, but the huge cost of pumping there must be giving the owners some anxiety.

On the basis of anything like the present level of prices and costs, the future looks hopeless, but I do not consider that the quotations for either metal represent in any way the intrinsic value. The holders of metals are raising cash at any sacrifice, actual consumption having fallen quite suddenly to a very low ebb. The banks cannot finance dealers, who would otherwise have held their stocks, and no one is buying who can postpone orders. The consumption in Europe is far below normal, despite the necessity of reconstruction, and the world's production has fallen to far below pre-war standards. The Broken Hill output ceased through the strike, and operations are not being recommenced because of low prices. The present level is now below that at which the Burma Corporation originally stated it could profitably produce concentrates. When the normal demand arises, there must be a serious shortage, and then both metals must appreciate in price to the point at which equipped mines can operate.

To illustrate this, the world's production of pig lead in 1913 was estimated at 1,142,264 tons, a drop of 130,012 tons on 1912. We have no information as to the output during 1919 from many countries, but there is now no considerable Australian production and the United States output has steadily fallen for the past four years; indeed, wherever there is any accurate information the output is down. I hardly think that the world's production at the present moment is more than 800,000 tons per annum. The statistical position of zinc is equally striking. The world's production in 1913 was about 980,000 tons, and in 1919 about 570,000 tons, and to-day is probably not more than 500,000, a generous estimate. When one considers the requirements for reconstruction in Europe, including England, it is quite evi-

dent that the present lack of demand is only temporary, and that there must be a rapid alteration in the situation.

Capital will not be attracted to the mining industry either here or abroad until there is some evidence of substantial profits, and we need not fear the opening of new fields at the present moment. After all, the smelters cannot produce lead or spelter without ore, and no ore will be raised if it does not pay to mine it. Personally I anticipate a fairly long period, say six months, before there is a steady consumption, and then there should be a period of super-normal demand, which may last several years. The important thing from our point of view is whether we can compete against foreign countries. This depends on the cost of labour and materials and the quality of our deposits. We have few natural advantages, and many artificial disadvantages, among which may be mentioned royalties, rates, taxation, and the cost of acquiring land and disposal ground. Evidence was given by our Association at the Non-Ferrous Metal Inquiry of the crushing nature of these, and recommendations were made to the Government, all of which have been ignored.

With regard to labour, I am more than ever convinced that a new and better standard of effort can be obtained if the mine-owners will seriously face the formation of Consultative Works Councils, with wages based on the success of individual mines as a whole. The present method of contracts underground is thoroughly bad, and is the antithesis of co-operative production. We want intelligent team work, and I am quite sure that if this can be achieved we shall increase our production per man by 20% to 25% without any slave-driving pressure. I have found that men respond readily if they only know the facts, and every man on the mine should be placed in the position of seeing the collective result of his effort. I should like to enlarge on this important factor, but the editor can hardly give me space.

Taking the lead and zinc mines in the United Kingdom, there were 1,501 underground workers and 1,475 surface workers in 1919. The effect of the existing conditions is that most of these will be on the unemployed list within a month or two. These figures include mines that were in course of development, with an abnormal number of surface workers engaged on the erection of plant, but if these non-productive mines are excluded the figures would of course be much smaller. My advice to mine-owners is to hold on as long as they can, as the present depression is quite artificial, and one hopes that the world will soon show signs of recovery from the destitution that is now its lot.

PERSONAL.

R. A. Archibald has left for Madras.

C. P. C. Beresford has recently been appointed consulting engineer to the interests controlled by S. I. Patino in Bolivia, and left England on December 31.

Max W. von Bernewitz has rejoined Walter Harvey Weed in compiling the "Mines Handbook." The office of the Handbook is at Tuckahoe, New York State.

A. E. Bidlake has gone to Oruro, Bolivia.

F. K. Borrow has left for the Frontino & Bolivia Company's gold mines in Colombia.

V. W. Boyle has left for Nigeria.

Dr. W. H. Collins has been appointed director of the Canadian Geological Survey.

V. J. Edwards has left for Portugal.

J. P. Grenfell is back from the Transvaal.

George A. Harrison, who was out for the Russo-Asiatic Consolidated, has returned from Siberia.

Ross B. Hoffmann is here from the United States.

Austin Y. Hoy, London manager for the Sullivan Machinery Company, is back from the United States.

J. H. Ivey has resigned as manager of the Poderosa mine, Chile, and is now in charge of the Corocoro Company's copper mines in Bolivia.

R. C. Jennings has gone to Venezuela.

C. E. Jobling is returning from Sweden.

A. A. Kelsey has left for Mexico.

N. S. Kelsey has been appointed manager of the Tomboy Company's mines in Colorado.

E. A. Knapp is expected from Nigeria.

W. J. Lakeland has gone from Burma to Ballarat.

F. H. Lathbury has gone to Selangor, Federated Malay States.

F. H. B. Leggett has gone to Burma.

W. J. Loring has been elected president of the American Mining Congress for 1921.

V. F. Stanley Low has gone to Sweden.

R. Macfee has gone to Algeria.

H. Mackay has gone to Colombia.

T. Bruce Marriott has left for South America.

J. A. McKinlay has gone to Burma.

A. H. P. Moline, manager of the Bendigo Amalgamated Goldfields, is visiting the United States.

J. W. Newbery has gone to Burma.

Eric Newbold has gone to New Mexico.

R. E. Palmer has gone to Spain.

Frank Powell is leaving for Colombia on January 18.

R. Allison Purvis has joined the staff of the Marmito Mines, Ltd., Colombia, and left on December 16.

R. Quance has gone to Dunkwa, West Africa.

Edgar P. Rathbone is with the Upper Silesia Plebiscite Commission, at Oppeln, Silesia.

William Russell, London manager for the Dorr Company, has returned from the United States.

W. P. Rutherford, managing director of the Tharsis Sulphur & Copper Co., has been appointed chairman in succession to the late Lord Glenconner.

D. A. Sutherland has left for South America.

A. E. Taylor has left for India.

E. O. Teale has left for Tanganyika Territory to make a new geological survey for the Colonial Office.

David M. Thompson, formerly an engineer with the Naraguta (Nigeria) Tin Mines, Ltd., has joined the board of the National Engineers' Supply Company, Ltd., of Liverpool.

E. F. V. WELLS has been appointed manager of the Tweefontein Collieries.

A. HEDLEY WILLIAMS is at the Lobitos oilfields.

E. W. SANDEMAN, secretary of Ipoh Tin Dredging, Ltd., died on January 1.

CURTIS H. LINDLEY, the eminent San Francisco lawyer, and the author of the handbook, "The American Law Relating to Mines and Mineral Lands," died last month.

MATTHEW T. WIGHAM, secretary of the New Rand, Ltd., and other companies, died last month. He was born in Northumberland in 1854, and joined the late T. J. Bewick as personal secretary, becoming subsequently secretary of some of Mr. Bewick's companies. For a short time he served in London in the same capacity with Bewick, Moreing & Co. Subsequently he became associated with the Hon. H. Finch Hatton. Of recent years he was known among mining engineers as the secretary of the New Rand, Ltd., Arthur Sawyer's enterprise for testing ground in the Orange Free State.

TRADE PARAGRAPHS

BOVING & CO., LTD., of 56, Kingsway, London, W.C.2, have issued a leaflet describing their low-lift pumps.

MILLARS' TIMBER & TRADING CO., LTD., of Pinners Hall, London, E.C.2, have issued a pamphlet describing their air-compressor, which is suitable for application for all sorts of purposes, for instance, rock-drilling, caulking, rivetting, and pneumatic painting.

THE INTERNATIONAL BARGE SUPPLY & TRANSPORT CO., LTD., of 5, Lloyd's Avenue, London, E.C.3, send us a pamphlet containing specifications and drawings of steel lighters and motor-driven barges, suitable for short coastal journeys or inland water traffic.

THE WESTINGHOUSE ELECTRIC INTERNATIONAL COMPANY, of 2, Norfolk Street, Strand, London, W.C.2, send us Motor Application Circular No. 7,132, which is devoted to a description of electrically-driven shovels used for digging and moving earth and broken rock.

HEAD, WRIGHTSON & CO., LTD., of Stockton-on-Tees, well known for their manufactures in connection with mining, such as cyanide vats, head-frames, tube-mills, Nissen stamps, etc., have commenced the manufacture of a number of metallurgical and mining specialties by arrangement with the Colorado Iron Works Co., of Denver. These are as follow: The Convertible Discharge Ball-Mill, a short mill fitted for either grate or open discharge; the Rod Mill, a cylindrical mill using rods instead of balls as the grinding medium; the Akins Classifier, a highly efficient machine of simple construction; the Impact Screen, a mechanically-operated high-capacity screen; the Lowden Dryer, a machine for handling flotation concentrate and other materials of a sticky nature; and the Skinner Roasting Furnace, a vertical multiple-hearth furnace of improved construction.

THE DORR COMPANY, of New York and Denver (London Office: 16, South Street, London, E.C.2), have issued Bulletin 19, describing the Dorr Washer. This machine is the result of a demand for a more economical installation, both in initial and operating cost, than was previously used for washing iron ores. While the washer was developed primarily for washing iron ore, it has a wide application in other fields for washing and classifying mixed, coarse, and fine materials such as gravel, crushed ores, etc. It is a combination of the Dorr classifier with a trommel partly submerged below the water level at the lower end of the classifier tank. As applied to iron-ore washing, the feed consists of the undersize from a grizzly, with the bars spaced about 6 in., and is introduced through a suitable hopper into the upper end of the trommel. The washed oversize is discharged from the lower end of the trommel with from 8% to 12% moisture. The undersize passes through $\frac{3}{8}$ in. or $\frac{1}{2}$ in. openings in the trommel into the classifier tank, where it is separated into two products. The coarse material is discharged at the upper end of the classifier with from 10% to 15% moisture after having been washed free from clay and the finer material, due to the action of the rakes and spray water added above the water level in the classifier. The fine silicious and clayey material overflows with the water, together with a small amount of fine ore, and is discharged to waste, or in some cases treated on tables. The concentrate consists of the trommel oversize and coarse product from the classifier.

METAL MARKETS

COPPER.—The downward course of values made further progress during the month of December. This, of course, was partly due to sympathy with the whole trend of world's prices, but at the same time the copper situation in itself has not been by any means a strong one. The big surplus stock held by the American producers still hangs as a kind of threatening cloud over the market, and the difficulty of disposing of this has necessitated further price cuts on the part of the producers in the United States. Meanwhile consumption both there and here has been quiet, and although consumers in this country are still fairly actively employed on old contracts, new bookings show a tendency to diminish, and with the price slipping away there is little inducement to buyers to take hold of any quantity of the metal. In the United States there is a general tendency to curtail production. This, however, will take some time to affect the situation of stocks. In the meanwhile, up to October at all events, in spite of the curtailment already in effect, production was apparently on a larger scale than in pre-war years. It is therefore not surprising that the big stock of copper which accumulated as a result of the cessation of the war has been difficult to disperse. Another thing which may have a considerable bearing on the situation is the tendency to reduce wages in many of the copper districts of America, thus automatically reducing the cost of production. Reports from Spain state that the Rio Tinto strike has been settled following upon the intervention of the Minister of War. The men, it is understood, accepted the company's terms, reserving the right to discuss certain features later. From reports in regard to the Cape Copper Company's operations it would appear that they have been shipping part of their copper to America for sale. It would seem that some changes are being made in selling arrangements in America. The output of the porphyry companies is apparently to be sold by Messrs. Guggenheim Bros. instead of the American Smelting & Refining Co. It is understood also that the latter company will lose the sale of the output of the Cerro de Pasco Copper Corporation, which will be handled by the American Metal Company, while the Tennessee Copper Company will transfer the sale of their product from the American Smelting to Adolph Lewisohn & Son. It appears that Mexico has lifted the export duty on copper ore going to the United States until the price of copper on the New York market is above 15 cents. It is reported from Melbourne that the directors of the Hampden Cloncurry Copper Mines have

decided to cease operations pending an improvement in the metal markets.

Average price of cash standard copper: December 1920, £75. 16s. 8d.; November 1920, £84. 18s. 6d.; December 1919, £103. 17s. 1d.; November 1919, £98. 18s. 9d.

TIN.—This market has as usual fluctuated, but not to an extent that is anything remarkable for this metal. In the earlier part of the month some strength was shown, but subsequently values eased off, touching the lowest levels since the great rise in February, 1920. The chief feature of interest has been the arrangement come to whereby the Federated Malay States Government takes over the unsold supplies from the smelters there at 115 dollars per picul, this figure representing a value of £236 landed here. It was also reported that the Dutch interests in Batavia were negotiating with the Straits interests with a view to coming to some agreement in regard to the maintaining of prices. From the fact that these two grades of tin, which represent such very important supplies, were going to be strongly held, it might naturally be supposed that strength would be seen in the market, but the opposite was the case. This must be attributed to the general pessimism and weakness in all markets everywhere, combined with the fact that the actual demand for the metal from consuming centres was poor. America has been working for some time on her stocks, and even the fixing of the price in the Straits does not seem to have induced her to buy on any important scale. Meanwhile consumption in this country is also poor, the tinplate industry being in a bad way. Works generally are slowing down in their operations and talk of stopping altogether. The standard market here is now virtually based on Chinese and English tin, the latter having been more or less a drug on the market, with the result that it was being delivered against standard contracts at the fixed allowance of £7 per ton. For both Straits tin and Banka tin on spot premiums are realizable, but even adding the premium for Straits on to the price of standard tin it has been obtainable on spot at considerably less than it could be replaced in the East.

Average price of cash standard tin: December 1920, £212. 11s. 8d.; November 1920, £241. 5s. 6d.; December 1919, £314. 5s. 1d.; November 1919, £283. 13s. 7d.

LEAD.—Like other metals the market for this article also came to lower levels during the month of December. The primary cause of this seems to have been liquidation of stocks of lead which under present tight financial conditions it was becoming burdensome to carry. Another feature, however, has been that America has been at times selling lead here, and arrivals have been fairly heavy not only from Spain, but also from America and Germany. It has been rumoured that smelting operations in Australia may not be recommenced quite so soon as was expected in view of the depression in the markets, but whether this be correct or not the report had no effect on the market here, the fact being that there is plenty of lead in sight for the moment, and consumptive demand has been poor. It is stated that owing to the decline in lead and zinc prices the board of the Broken Hill South mine wish to have time to review the situation, and all productive operations except the slime plant are discontinued until January 10. It seems to be generally anticipated that early in the New Year the demand for manufactured lead products will revive, but this of course remains to be seen, and meantime it looks as if the trade might be able to subsist upon the arrivals continually coming in without making any great inroads upon the stocks in this country, which increased by over 4,000 tons during the month of December.

Average price of soft pig lead: December 1920, £24. 11s. 10d.; November 1920, £32. 5s. 6d.; December 1919, £41. 7s. 8d.; November 1919, £34. 16s.

SPELTER.—This metal also declined to a marked degree during the month of December, the price indeed coming to quite a normal pre-war level. As in the case of other metals, the chief reason has been the paucity of demand from consumers, the galvanizing trade having experienced a great lack of fresh orders. Meanwhile Germany has been selling. At one time some demand was experienced here from America, and it is understood a fair line was sold to that country. This business was of course attracted by the comparatively low prices ruling here. Of course America has plenty of spelter of her own, and the removing of supplies of the metal to a producing country is rather an

abnormal feature. Dealers could, however, buy in this country at less money than in the United States and so buying orders came to this side. At the moment the whole situation is rather difficult to read. The price is admittedly low, but as already stated the demand is poor, and further offers may yet be seen from the Continent. It appears that the Federation of Belgian Producers has fixed a selling price at 182·50 frs. per 100 kilos, working out at something like £34. 15s. London terms. This price is of course far above the market level here, and it seems doubtful whether the Belgian producers can hold on till the market recovers to that level. It is understood that the Electrolytic Zinc Company's works at Risdon, Tasmania, are ceasing operations till the metal markets improve, although constructional work will continue. The Welsh zinc smelters are still closed, and there is little likelihood of any resumption of work for some time to come.

Average price of spelter: December 1920, £28. 11s. 6d.; November 1920, £35. 14s. 7d.; December 1919, £53. 9s. 2d.; November 1919, £46. 17s. 3d.

Zinc Dust.—High-grade Australian zinc dust is quoted at £70 to £80 per ton, with English at £75 to £85 and American at £70 to £80.

Antimony.—English regulus of ordinary brands is quoted at £42 to £45 per ton, and special brands at £43. 10s. to £48 per ton. Foreign regulus is easy, and can be had on spot at about £35 per ton.

Arsenic.—Business is quiet and the market is easy, the price being about £55 to £60 per ton for Cornish white.

Bismuth.—The quotation still continues at about 12s. 6d. per lb.

Cadmium.—The current quotation is about 6s. to 6s. 6d. per lb.

Aluminium.—For home and export the price rules at £165 per ton.

Nickel.—The price stands at £215 for home and export.

Cobalt Metal.—The present quotation is about 27s. to 30s. per lb.

Cobalt Oxide.—Black oxide is quoted at about 17s. 6d. and grey at 18s. 6d. per lb.

Platinum.—The market has been weak, and the quotation is now about £16 per oz.

Palladium.—The demand for this metal is also slackening, and the price is quoted at £16 per oz.

Quicksilver.—This metal has only been in very quiet demand. The price of Spanish was reduced by the leading interests to £14 per bottle, and later to £12 per bottle, afterward recovering to £12. 10s.

Selenium is still quoted at from 10s. 6d. to 13s. per lb.

Tellurium is also unaltered at from 95s. to 100s. per lb.

Sulphate of Copper.—Prices are rather easier, and now stand at about £38 to £40 per ton.

Manganese Ore.—The quotation is about 2s. 6d. per unit c.i.f. U.K. or Continent.

Tungsten Ores.—Wolfram 65% is quoted at about 17s. 6d. to 18s. 6d. per unit c.i.f.

Silver.—On December 1 the quotation of spot standard bars was 44⅝d. per oz., values declining until they touched 38⅞d. on December 10, rising again to 43d. on December 29. At the end of the month the quotation was 40⅝d.

Graphite.—There is little fresh in this market. The price of soft velvety flake 85 to 90% is about £60 to £80, and Madagascar 80 to 90% about £21 to £25 per ton.

Molybdenite.—85% is quoted at 55s. to 60s. c.i.f. U.K.

Chrome Ores.—The current quotation for 48 to 52% is about £8 per ton c.i.f.

Iron and Steel.—These trades are in a somewhat transitional state. Prices were of course abnormally high during the boom period, and the readjustment has been slower in these than in the case of most other commodities. With demand falling off, and much lower prices being quoted for both pig iron and steel by Continental countries, it was inevitable that the prices of home makers should be readjusted. Cleveland ironmasters early in January met the situation by marking down their prices by 10s. to 20s. Makers of manufactured material are naturally easier in their attitude as regards prices, and although reductions have been made in certain descriptions and makers generally are willing to book actual orders when these are submitted at shaded quotations, a more general marking down in prices seems still to be due.

THE MINING DIGEST

A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

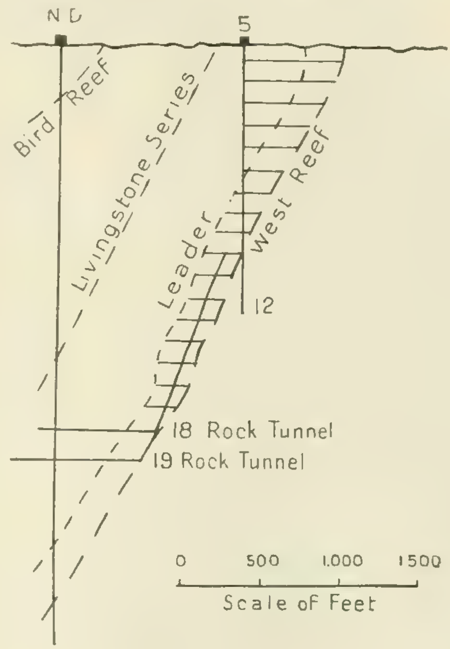
In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also reviews of new books, and abstracts of the yearly reports of mining companies.

NEW DEVELOPMENT METHODS AT RANDFONTEIN CENTRAL.

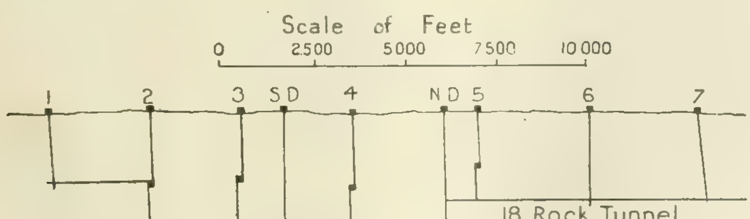
The November *Journal* of the South African Institution of Engineers contains a paper by G. H. Beatty on the new shafts and development methods at the Randfontein Central. These new methods were adopted after the acquirement of control by Barnatos from Sir J. B. Robinson.

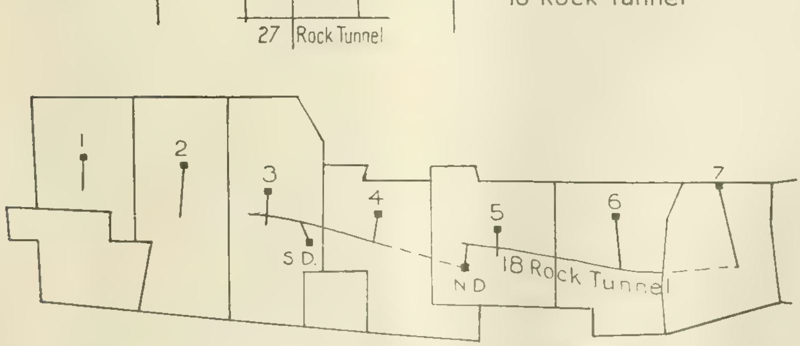
The portion of the Randfontein group of mines affected by the new lay-out consists of seven sections—numbered 1 to 7—from south to north on the strike of the reef series. Mining operations are being carried on in sections Nos. 2 to 7, along a strike of 17,000 feet. With the old lay-out, hoisting and pumping were conducted in all sections through ten shafts, namely, the Nos. 1, 6, and 7 main inclines, No. 2 sub-incline, and Nos. 3, 4, and 5 main verticals and sub-inclines. Until 1918 the No. 7 section was served by a main compound shaft and sub-incline. In that year the sub-incline was connected to the surface, and the compound shaft was cut out. The ten shafts were served by 19 hoists, and employed 54 engine drivers, 54 skipmen, 20 banksmen, and 30 shaft timbermen. The average monthly tonnage hoisted during the year 1919 was 103,000 tons, at a hoisting cost of 2·363s. per ton, from an average depth of 2,300 ft. In September, 1917, a start was made upon the sinking of two new verticals, known as the North and South Deep shafts, the object being to cut out all nine shafts in sections No. 1 to 6.

There are two reefs, 200 ft. apart horizontally, with a very even strike roughly north and south, and a regular dip averaging 65°. Dislocations are rare, and the few faults and dykes in evidence are not of much importance. The gold is evenly distributed, and about



Cross-Section of Reefs.





Sketch Plan of Shafts and Rock Tunnels.

85% of the ore developed is stoped. With the exception of the steep dip, these conditions are favourable, but, on the other hand, the reef channel is very thin, the hanging and foot-walls are difficult to support, and the present workings are subject to great pressure and movement, due to depth and the fact that practically all the ore above them has been stoped out and no support provided.

The design of the new shafts has already been the subject of a paper read by W. L. White and published in the *Journal* in February, 1919. (See the MAGAZINE for April, 1919.) They are designed and situated so as to serve an ultimate depth of 5,000 ft. They are placed in a position to intersect the reefs midway in the area between the present lowest workings and that depth. With a dip as high as 65° no great amount of cross-cutting is necessary from the shafts to the reefs, even on the top and bottom levels

Under the old shaft lay-out, five inclines were being sunk to exploit the area, namely, the No. 6 main incline and Nos. 5, 4, 3, and 2 sub-inclines. They were very difficult to sink, and progress was painfully slow owing to the awkward dip and delays caused by breakdowns in the pumping and hoisting plants.

The old method of development was the usual practice on the Rand, and consisted of cross-cuts from the shaft stations to the reefs, reef drives, and connections between drives at intervals. The vertical distance between drives was about 120 ft. This method proved costly, inadequate, and totally unsuited to the local conditions, for the following reasons: (*a*) Limited speed and high cost or driving on reef, because when a drive had advanced some distance the operations behind it retarded its progress. Almost immediately stoping commenced it became necessary to timber the drives. Pillars left above the level were useless and dangerous, and consequently a quantity of rock was always broken directly on to the level. This resulted in constant injury to the water and air supply pipes, difficulty in feeding the machines, and delay in cleaning out the development end. (*b*) Cost of supporting drives. With several stopes working above and below any drive, it became necessary to close-timber it practically from end to end, and the timber had to be renewed several times per annum. (*c*) Cost of tramming. The track was subject to injury through blasting operations and falling rock. As before mentioned, the dip is 65°, and with sufficient foot-wall cut away to support the track, the foot-wall of the upper stope became troublesome, and the stoping width above the drive difficult to control; further, the development rock value was reduced to practically nothing. With insufficient foot-wall cut away the track sagged immediately stoping commenced below the level. Owing to pressure, no regular grade could be kept on the track, and in stoped areas the track became a switchback. Rock from inside stopes had to be trammed through congested drives and past numerous box-holes, through which water and fines were falling, with resulting derailments. (*d*) Limited output from any one drive in a given time, due to reasons given in (*c*) and (*f*). (*e*) Length of time each drive had to be kept in commission, due to (*d*). (*f*) No mechanical means of transport was possible through the reef drives. (*g*) Mine water could not be kept on the level on which it was struck or used, and found its way to the lowest stoping level, becoming very muddy in its progress. (*h*) The cost of support and tramming increased with the age of the level, and toward the end of its life, the inside stopes —probably one or two faces only were working—had to bear the whole cost of upkeep. Unless they were rich they were unpayable and abandoned. (*j*) It was difficult to control air currents and the ventilation was unsatisfactory in places. (*k*) Loss of compressed air in friction and leakages; 140,000 ft. of air pipe was in commission in the reef drives, all of it liable to damage from many sources. (*l*) The workable length of a drive on reef was limited, and a shaft could serve a limited strike only.

The new method introduced is as follows: A heading termed a "rock tunnel," size 8 ft. by 8 ft., is driven from 30 to 50 ft. in the foot-wall of the lower reef, and cross-cuts are driven to the reefs at intervals of 500 ft. The levels are connected by means of winzes and rises from the intersections of reefs and cross-cuts. Reef drives are driven at leisure as the stope-faces advance. The distance between levels is 174 ft. vertically, giving 200 ft. to 210 ft. backs. The rock tunnels are provided with either 10 ton electric locomotives, of the overhead wire type, or smaller battery locomotives. Sidings for ten 30 cwt. cars are provided at each cross cut.

The advantages of this system are as follows: (*a*) Ore can be developed rapidly, as there is nothing to hinder the rapid advancement of the rock tunnel. (*b*) Each stope-face has an independent drive, there is no tramming past box-holes or through congested drives, and the average length of hand tram to the rock tunnels is 270 ft. only. When the stope-face is worked out, it is reclaimed, washed, and abandoned, together with its drive. (*c*) Given adequate means of transport, the rock tunnels can easily handle the rock broken in the stopes feeding them; their life is, therefore, determined by the rate at which they can be driven, and the rate of exhaustion in the stopes. Concentration is thus possible in a high degree, and the life of a level and the number of levels in commission are reduced to a minimum. (*d*) The main air and water supply pipes are situated in the rock tunnels, and out of harm's way. (*e*) Mine water is led to the rock tunnels, which are provided with concreted drains. (*f*) There is no difficulty in controlling air currents, and ventilation is improved. (*g*) The rock tunnels can be of great length, with very little disadvantage. Transport of rock, material, or men through them presents no difficulty or undue expense. The rock tunnels going north from the North Deep shaft will be 6,000 ft. long. Locomotives travelling at eight miles per hour bring the most distant workings within nine minutes of the shaft. (*h*) It is evident that the method has a beneficial effect upon the grade of the ore crushed. The value of development rock from main drives driven on reef averages only about 2·5 dwt. per ton, even when the reef is carried in the correct position in the drives. But with a steep reef a degree of accuracy is necessary which is not obtainable under present-day conditions, with the result that an unnecessary amount of waste is broken at times. Flaking commences as soon as stoping is in full swing and weight thrown upon the lengths of drive between stope-faces, and the drives are constantly increasing in size until finally stoped out. It is probable that the rock broken in drives, plus subsequent additions of waste, averages under 2 dwt. per ton. The new shafts are provided with waste bins on every level, and the waste broken in the rock tunnels and cross-cuts is trammed and hoisted as waste. The waste broken in the reef drives is easily controlled and kept at a minimum; in most cases the reef drive is no more than a ledge, wide enough to support a 2 ft. track, cut in the foot-wall.

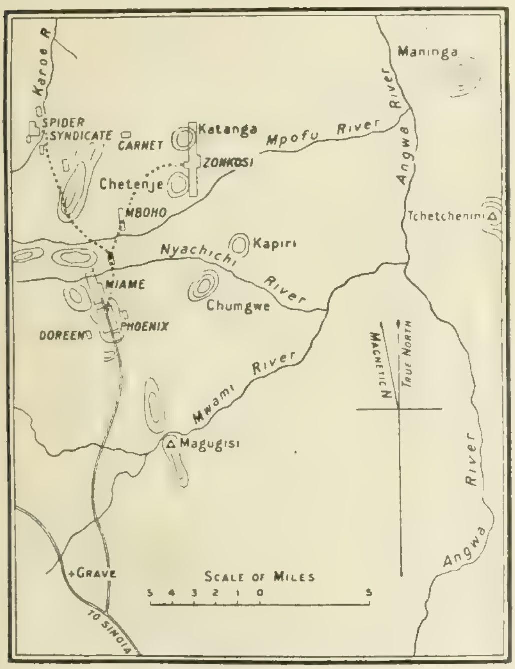
The method eliminates the working defects and limitations of the old system, and permits of two shafts serving a strike of 14,000 ft. for rock concentration and hoisting purposes, and an additional 6,000 ft. for drainage. Further, it greatly increases the tonnage that a

given area can produce in a given time. The area in question, Nos. 2 to 6 sections inclusive, may be called upon to produce 1,700,000 tons per year. To develop that quantity of ore it will be necessary to drive 14,000 ft. of rock tunnel annually, and to break and handle the tonnage it will be necessary to have 28,000 ft. of rock tunnel in full commission. Not more than four levels will be in commission at one time; probably two will be in certain stages of exhaustion, one in full commission, and one opening up.

It may appear that the points of attack for development purposes are insufficient for such a large area. Roughly speaking, the strike is divided by the shafts into stretches of 4,000 ft. at the southern end, 4,500 ft. between shafts, and 5,500 ft. at the northern end. Thus, as the middle portion will be attacked from two ends, there will be four points of attack until the middle portion is developed, and two afterwards, or, say, an average of three over the development life of the level. If development work is confined to the single-shift basis, it will be necessary to have twelve ends working, or four levels in course of development.

MICA DEPOSITS IN LOMAGUNDI, RHODESIA.

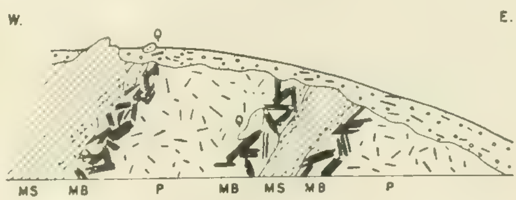
A report has been issued by the Rhodesia Geological Survey, written by the Government Geologist, H. B. Maufe, on the mica deposits, recently developed, on the western flanks of the Angwa river basin in the Lomagundi District of Rhodesia. The majority of the claims are situated between the Mwami and Mkwichi rivers, tributaries to the left bank of the Angwa river. The area over which the mica claims are scattered measures more than 40 square miles, but the limits of the deposits are not known. The deposits are only a few miles east of the probable route of the proposed Sinoia-Kafue Railway, and is about 64 miles from present rail-head at Sinoia.



Sketch Map of Mica District.

The country-rock is a well-foliated mica schist remarkably uniform in composition. On the rough edges of the rock glassy quartz in grains and small lenticles may be seen lying between the mica scales, but it seldom seems to form as much as half the rock. The chief variation from the mica schist is due to the incoming of quartzite or quartz schist bands. These consist of grey, micaceous quartzite from a fraction of an inch to several feet thick. Usually a number of bands of quartzite are separated by bands of mica-schist, and in places the alternations are so rapid that the rock might be described as a striped schist. Some bands contain a little biotite in addition to muscovite. A fine-grained grey porphyritic biotite granite crops out at the northern end of the Miame claims. As is so frequently the case, a stream follows the contact between granite and schist, and the granite was not actually seen to be intrusive into the schist. A grey felsite and a small outcrop of diorite similar to that seen in the Angwa river on Romsey farm were noticed in the small stream running into the Karoe river.

Pegmatite dykes contain all the merchantable mica. They commonly trend in a direction a few degrees west of north, but cannot often be followed for as much as 100 yards without setting off to the east or to the west. They vary in width from a few inches to 10 or 15 yards, and over much of the field they dip to the west at high angles. In the north-western part of the field called Dounka, situated around the Karoe (north) river, the dykes dip east at a high angle and are on the average narrower than elsewhere. The mica books occur in the dykes in a remarkably regular manner, which assists considerably prospecting and mining. The books occur in a belt or in a succession of lenticles against the mica schist walls, and usually on both sides of a dyke, as shown. Otherwise the dykes present the many variations of composition so characteristic of pegmatites. The commonest variety of pegmatite is one consisting almost entirely of felspar, the quartz occurring inconspicuously in glassy grey blebs scattered through the felspar, which is itself decomposed to a pinkish, buff, or white earth. This kind of rock usually forms the central portion of a dyke. In some instances it has scattered regularly through it books of mica lying at all angles. The books are large, but very thin. The mica is stained a dark colour and does not yield a marketable grade. In portions of some dykes, and usually near the walls, the quartz becomes more abundant than the felspar and forms lenticles or blows. These quartz blows are occasionally free from felspar, but contain numerous books of mica an inch or two in length. This variety is known on the field as greisen. It usually lies close beside, or is mixed with, the pockets of workable mica. Since this greisen resists decomposition and disintegration, it forms blocks at the surface, and is frequently



Pegmatite Dykes with Books of Mica.

the only indication of a pegmatite dyke. In prospecting greisen may be taken as an indication of a possible mica-bearing dyke beneath.

The mica is wholly muscovite, chemically a hydrated silicate of aluminium and potassium. It is usually either of a ruby or of a bottle-green colour, though some clouded silvery mica has been found. The statement that marketable biotite and phlogopite have been found is not substantiated. The native name for the mica is "datsi." The books of mica occur in a band or in a series of lenticles on each wall of a pegmatite dyke, the books lying at all angles, but often touching one another and even being closely packed. The band or lenticle is in places close to the wall of mica schist country-rock, in others separated from it by a few inches of pegmatite. Here and there a dyke is seen with only one band, but this is unusual, except in the case of the narrower dykes. Inclusions or horses of mica schist country-rock are very common in the dykes, and it is usual to find a zone of mica books completely surrounding the horse, which is thus a structure not unwelcome to the mica miner. The books vary in size from 4 to 5 in. in length to as many feet, the majority probably being between 6 and 18 in. They are seldom more than 6 in. thick, and frequently half that. Much of the mica is stained, near the surface deeply stained, but mining seems to show that staining diminishes 10 to 15 ft. down, and the mica becomes slightly stained, spotted, or clear.

All work is open-cut, and at the time of Mr. Maufe's visit had not gone below a depth of about 35 ft. Much of the work is done by pick and shovel, the felspar of the pegmatite being decomposed to a clay and therefore easy to work. When blasting has to be resorted to, either 30% or farmer's dynamite is used for loosening the rock without shattering the books. The pegmatite dykes are on some claims so closely placed that it is economical to take out together the foot-wall band of mica, the intervening strip of mica-schist country-rock, and the hanging-wall band of mica in the next dyke. In other cases the two bands belonging to the one dyke are worked together, or each band is separately worked. The books commonly split up on being taken out into slabs about ½ in. thick. These slabs are taken to the dressing ground, and first split up with the aid of a knife into sheets about $\frac{1}{32}$ in. thick. They are next trimmed by shears into irregular polygonal shapes, all cracks, flaws, and striations being rigorously cut away, and the faces of the sheets peeled until a smooth even surface is obtained. Bent or buckled mica should not be split at all, but rejected. The trimmed sheets are taken to the grading sheds, where this most important operation is carried out. The groups depending on transparency recognized lately by the Ministry of Munitions are: Clear, part stained, 2nd quality clear, 2nd quality part stained, fair stained, ordinary (rust and clay stained), densely stained, black spotted, and soft white. Generally, however, only four groups are recognized, namely: Clear, slightly stained, stained, and densely stained. In each group there are ten sizes, depending upon the largest rectangle which a sheet can give. The largest size is 72 in. square or over. It is estimated that 1½ lb. of trimmed mica is a good average yield from each hundredweight of mica won. The waste is therefore enormous. Much of this waste is of marketable quality, and could be converted into splittings for the manufacture of mica board, mica cloth, or mica paper, while other portions could be pulverized to form ground mica.

Mr. Maufe gives the following general conclusions: (1) The quantity and quality of the mica over a large area in Lomagundi are sufficient for the establishment of a regular mica-mining industry. (2) The mica is more regular in its distribution in the dykes than is usual in pegmatites. The deposits are seldom pockets, but are generally sufficiently continuous to be called "reefs," as this term is understood in South Africa. (3) The mode of occurrence of the mica, and the ease with which a marketable product can be obtained without much capital, makes the work suitable for the "small man," and in view of the large number of reefs scattered over a wide area it may be confidently anticipated that continual efforts will be made to work the mineral.

REINFORCED CONCRETE IN TIN-DRESSING PLANT.

At the meeting of the Cornish Institute of Engineers held on December 18, Ernest Gordon read a paper describing the use of reinforced concrete in the construction of the 100-ton mill and dressing plant at the Porkellis (Basset & Grylls) tin mine near Wendron. It was decided to use reinforced concrete on account of the high price of timber.

A cheap and effective form of reinforcement was obtained by using the strands of old scrap winding rope. This rope, 1½ in. diameter, was unstranded by hand in 100 ft. lengths, there being 6 resulting strands of roughly ⅜ in. diameter. No attempt was made to straighten out the twist in the strands; but, in order to free them from grease, they were coiled up and heated in the firebox of a boiler. The strands were very stiff and strong. A rough idea of their strength may be gathered by assuming that the original breaking stress of the rope, when new, was 60 tons, and, assuming that the present strands were half worn through, the breaking stress would be about 5 tons. The sand used was ideal for the purpose, being the washed refuse of the old alluvial tin streamers. It was composed chiefly of sharp quartz grains from ⅛ in. down in size, and contained no slime or earthy matter. The cement used was the ordinary Portland cement, which has been taken in the following costs at £5 per ton on the mine.

A wheelbarrow was taken as the standard unit for measuring the ingredients. In estimating the cubic contents of the final mixture, no allowance should be made for the cement, as the latter is so fine that it fills up the voids without appreciably adding to the volume. One cubic foot of cement is taken at 90 lb.

Great attention was paid to mixing, and all batches were turned over three times dry and then three times wet. It was found that by using little water the moulds could be freed more quickly, but this practice was given up as the cement lost so much of its strength, due to the difficulty of efficient packing in the wood moulds. Cement is quick setting by using hot water, the chemical action being hastened. This is useful in an emergency, but the resulting concrete is not ultimately so strong as that produced by the natural slow process. The best result is obtained by keeping the mixture moist for several days. Frost has a bad effect if the mixture freezes before it has had time to set, the result being that a spongy mass is formed owing to the included water expanding on becoming ice. To avoid this, straw was on one occasion placed around an important loading with successful results. Another method is to add common salt to the water before mixing in order to lower the freezing point. This, however, is not good practice. Thorough packing is most essential; for, if this is scamped, numerous voids are formed, with a corresponding loss of strength.

In compression concrete is very strong, but in tensile strength it is only, as a rough guide, equal to a twen-

tieth the strength of timber; consequently the added reinforcement should be equal to dealing with the load alone.

At the main shaft a 100-ton ore-bin was made of concrete. This ore-bin had to be connected with the mill 900 ft. away by a double tramway with an endless rope system of haulage. A cutting was made through some fields, and a gantry, 228 ft. long and 23 ft. high at the highest point, was erected. All the fence posts, sleepers, and gantry legs were made of reinforced concrete. The fence posts were of the ordinary type now becoming so common. They were 6 ft. long, 3 in. square at the top, and 5 in. square at the bottom end; 5 holes were cast in each for the fencing wire to pass through. Several moulds were made of wood, casting 6 posts at a time.

The mixture used consisted of one part cement to four parts sand. Reinforcement was made by two strands of wire rope, embedded in the mixture, one on either side of the holes. The holes were formed by five ½ in. iron rods which passed through all six posts. As soon as the mixture started to set, these rods were drawn out, leaving behind them nice clean holes. The cost per post for labour and material worked out at 1s. 1d. The weight is about 100 lb. each. They were sunk into

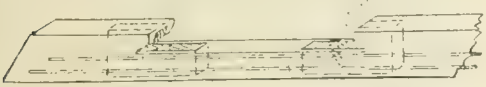


FIG 1. CONCRETE SLEEPER.

the ground 18 in., and set 8 ft. apart. The fencing wires used were old winding rope strands, the ends of which were fastened together by an ordinary fishplate bolt with two specially turned-up washers to clamp the strand on either side of it.

The sleepers were 8 ft. long, 5 in. wide, and 4½ to 3½ in. thick between the gauge; designed for two 1 ft. 6 in. tracks of 4 ft 6 in. centre. The wood moulds were made tapered so as to draw out. They differed in this respect from the moulds for the posts, which had to be taken apart after each cast. A mould would cast 5 sleepers at a time. The mixture was four to one, and the reinforcement was again made by two strands of old wire rope embedded close to the bottom of the sleeper. It will be seen from the sketch that the rail is held in position by means of an ordinary iron dog on the inner edge, the outer being wedged up against the concrete sleeper. To strengthen this portion, as well as to allow for a dog to be driven, special blocks of wood were cast as shown. Before placing these blocks in the moulds they should be thoroughly soaked in water. Otherwise they will swell and crack the concrete before it has had time to set. They should also be treated with some form of wood preservative to prevent dry rot. In moulding, a small piece of the rail to be used was set on the top of the mould in position. This held up the wood block while the material was being rammed. When the ramming is completed the rail can very soon be withdrawn, and the impression left in the concrete. The cost per sleeper for labour and material worked out at 1s. 8d. The weight was about 150 lb. A timber sleeper of this size would have cost 2s. 9d. on the mine. The concrete sleepers were found to be easy to lay, as the gauge was already fixed. Moreover, as they grasped the rails firmly, they could be placed at intervals of 5 ft. So far the only disadvantage is the weight. As the cars in use are only 10 cu. ft. capacity the comparative lack of resilience is not of importance.

In the construction of the gantry, timber was used for the road bearers and the legs were made of reinforced concrete. These legs vary in height from 9 ft. to 19 ft. 7 in. Those over 9 ft. were strengthened by a horizontal tie as shown in the sketch. The legs are of 12 in. by 9 in. section with a batter of 2 in. to the foot, and the caps 9 ft. long of 15 in. by 9 in. section. Four bolt holes were cast in the cap for bolting down the road bearers, and a bolt was cast in each end to support the hand rail. The foundations were so made that their tops came to certain fixed levels, to reduce the

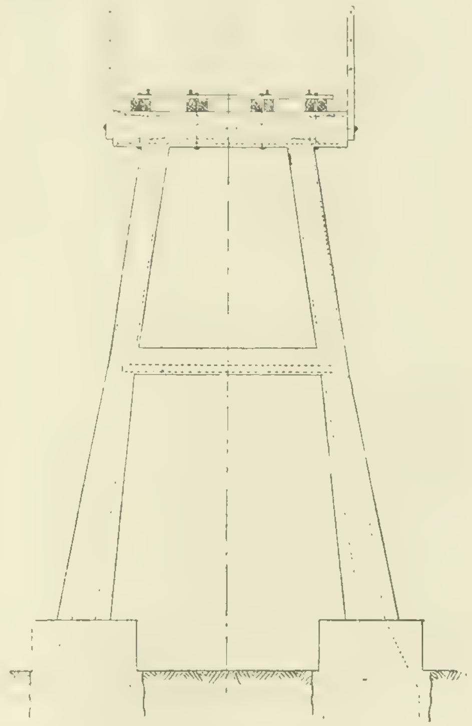

FIG. 2. CONCRETE GANTRY LEG: REINFORCEMENT SHOWN IN DOTTED LINES.

legs to standard lengths. The bottom half of the legs, up to and including the horizontal tie, was made first; and, after this had set, the top half of the mould was fixed and the work completed. The mixture used was four to one, and the reinforcement consisted of four strands in each limb. These strands, set in each corner, pass right down from the cap to the bottom of the foundation. The cross tie had 3 in. iron pipe filled with concrete placed an inch or so above the bottom, and this reached to the centre of each limb. The cap was strengthened by means of two 1½ in. iron pipes (also filled with concrete) embedded near the bottom, one on either side of the bolt holes. Under the top there were four horizontal strands, besides two which crossed the cap diagonally downwards. The cost of a 9 ft. leg including labour and materials came to 32s. 6d. against 66s. 5d. for one made of timber. The legs were set at 12 ft. centres apart, and all the woodwork on top was boiled in tar to preserve it.

To keep the haulage rope off the ground, rollers were made from lengths of 3 in. iron pipes. The spindle was held in position by a thin disc of concrete at either end of the pipe, the intervening space being filled with straw and paper. The weight of one of these rollers was just

over one pound, which compared favourably with one made with solid wood core, and the cost was about one half.

For the foundations for Holman's pneumatic stamps, after excavating to good solid ground, a 3 ft. base with plenty of area was formed of 14 to 1 concrete. From this base the main loading was formed. For the first 2 ft. a mixture of 8 to 1 was used, for the next 2 ft. 6 to 1, and finally a mixture of 4 to 1 brought the loading up to the anvil blocks. Owing to considerable trouble having previously been experienced through having wood blocks under the coffers, these blocks were dispensed with. Heavy cast-iron anvils were substituted to distribute the blow from the stamp over a sufficiently large area. A layer of hot pitch was used on the under side of the anvil; and, on the top of this, a ⅜ in. rubber mat

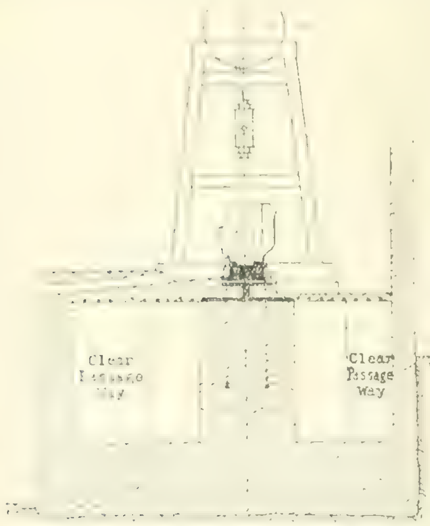

Fig. 3. Foundations for Holman Stamps.

was inserted. This arrangement has increased the stamp's output by 8% over the wood blocks, other conditions being equal. Foundation bolts were brought right up through the anvil and coffer, long washers taking the head of the bolts well above the discharge. Consequently, should these nuts become loose, they can be readily tightened without stopping the stamp. The reinforced concrete floor in front and behind, as well as the concrete-formed tray round the coffer, render the loadings quite dry beneath, so that inspection can be done with ease and comfort.

The concrete loadings for main belt drives were standardized, the ends of the original box being used time after time. The same applied to the crow-hole boxes which were all made tapered to permit their withdrawal. The horizontal launders which passed through the ends of the box were removed as soon as the mass started to set. All these launders were well soaked in water before using; otherwise they would swell and be difficult to extract.

For light walls for the wood buildings to rest on to bring them well clear of the ground, a mixture of 8 of stone, 6 of sand, to 1 of cement was used. This mixture, even with large stones added, gave a surprisingly strong result.

Several experiments were made in the making of concrete floors. It was found that good results were obtained by laying the ground over with stones from 3 in. to 4 in. cube and beating them well in. A layer of concrete was then added consisting of 6 of rough sand, 1 of fine sand, to 1 of cement. This mixture ran down between the stones, cemented them together, and formed a layer on top about 1 in. thick. When this had been roughly smoothed over, dry cement was sprinkled and a good hard face produced. It was found that a bag of cement (11 bags to the ton) would cover 80 sq. ft. of floor area.

The ore-bin behind the stamps was of the usual wooden V type with sloping bottom. It was found to be less expensive to cover the bottom with a layer of ferro-concrete rather than buy scrap sheet iron or boiler plates. A few iron sheets have been bolted on the top of the concrete where the actual blow comes from the dumped

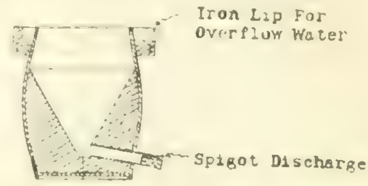

Fig. 4. Conical Dewaterer.

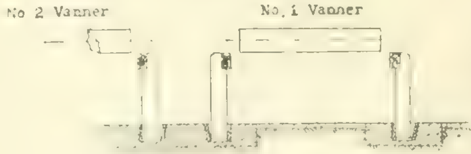

Fig. 5. Section of Vanner Loadings.

ore. So far the lining has shown no signs of wear, and the whole bottom of the bin has been made quite impervious to slime.

For the concrete stack for the Brunton calciner, an old iron stack 18 in. diameter, 18 ft. long, was used as the core. To avoid the concrete cracking, through the expansion of the iron from heat, straw was bound around it so as to form an air space. After the iron stack had been erected with its straw lagging, an outer mould 22 in. diameter and 3 in. long was centred and filled with 4 to 1 concrete. When this had set the outer mould was loosened, raised 2 ft. 6 in., and again filled. In this way the stack was built up in sections to the top. When in the course of time the iron core perishes through corrosion by gases, the concrete should take its place without interruption. Before this work was decided upon, a test was made to see how a similar mixture of concrete would stand the action of the hot gases; also to test the expansion of an iron core lagged with straw.

A section is shown of an oil barrel converted into a dewaterer. The concrete ring for the overflow water was cast in position, a few nails being driven into the barrel to prevent the concrete from slipping. For this ring a mixture of 4 to 1 was used, as well as a few single wires as reinforcement. Practically the only expense attached was in making the wood mould for the ring; but, once this has been made, it can be used time after time.

On dismantling Frue vanners, it is usually found that the sills have become rotten through the lack of ventilation from being embedded in concrete. The section shows the arrangement of vanner loadings recently put in, from which it will be seen that a considerable amount

of concrete has been saved as well as the sills. The wood box which surrounds the tenon and tightening wedge is made of rough timber. The concrete contracts around the box and tends to make the leg very secure.

The main shaft ore-bin, designed for a capacity of 100 tons, was rectangular in construction with a flat bottom. The front side rested on 4 pillars which also supported the floor of the bin to enable the cars to come underneath for filling. The landing stage and roof of the previous wood ore-bin, as well as the crusher loading, have been combined in the general design.

A ferro-concrete tank of 3,000 gallons capacity was made for gas engine cooling water. This tank was 6 ft. deep with sides 6 in. thick at the top and 9 in. at the bottom. Four pillars supported it 10 ft. off the ground. A mixture of 4 to 1 was used throughout the entire tank. Owing to considerable vibration being present, great care had to be taken with the reinforcement. A mesh of winding rope strands was made, set 6 in. apart, for the bottom of the tank. The strands were bent to continue up in the sides where they were woven with horizontal strands placed a foot apart. The strands were all placed as near the outside edge of the tank as possible. It was found on trial that the tank leaked slightly. By washing the inside with a mixture of lime and cement no trouble has been experienced since. The tank was braced on top by four ferro-concrete bearers which supported the water cooler. The cooler consisted of 12 poilite sheets placed horizontally one above the other, the water being made to cover the area of each.

Two travelling beams were constructed, of 23 ft. and 16 ft. 4 in. centres, for use over the gas engines. They were more or less experimental. They were reinforced with steel rails and lengths of complete wire rope. The latter was distributed throughout the beam in such a way as to break up the neutral axis. The mixture used was three to one; special care was taken in selecting the sand. So far they have answered their purpose well and were most useful when erecting the engines.

A number of concrete blocks were cast, 1 ft. 6 in. by 9 in. by 9 in. thick, hollowed out to leave 3 in. sides. These blocks were found very useful for quoins; moreover, being hollow, they were light for getting into position. When in position they can be filled with a cheap mortar which also serves to key them together. They were made in wood moulds which were fastened together by cottar bolts. The wood cores were made with plenty of taper, and well soaked in water before using. The mixture was 4 to 1. Very little water was used, so as to allow the cores to be withdrawn soon after packing.

Connecting Surface and Underground Surveys.— The method of connecting surface and underground surveys in connection with two shafts at the Throckley colliery, Northumberland, formed the subject of a paper read at the meeting of the Associates' and Students' Section of the North of England Institute of Mining and Mechanical Engineers, held at Newcastle-upon-Tyne on November 27, by Joseph Eltringham. The following account is taken from the report of the paper published in the *Iron & Coal Trades Review* for December 3. These two shafts are known as the Derwentwater and the Margaret respectively, and are some distance apart. The depth of the main seam is 243 ft. The plans of the separate pits having been laid down to the magnetic base by the magnetic-needle method and a holing effected between the two pits, it was decided to connect the two systems and so check the respective plans. For plumbing the shafts, a hand-manipulated drum was used, with wire 0·058 in. diameter, a pulley and cross-beam for lowering two weights (small and large), and a bucket containing engine oil. Operations commenced at the Derwentwater pit. The cross-beam was erected at the top of the shaft, and the pulley wheel was fixed in position so that the running-off side was in the centre of the shaft. The drum was then fixed on the pulley-wheel platform and the wire with a small weight attached passed over the pulley and gently lowered. When nearing the level where underground operations were to commence, the lowering ceased to allow for further elongation of the wire when the heavier weight was suspended. The wire was further lowered to the required position and the weight placed into the bucket containing oil. The weight was not allowed to immerse completely, so that any further elongation of the wire could be readily detected. To lessen the oscillations due to air currents the fan was stopped for a short period. A 6 in. transit theodolite was next set up near the shaft-bottom and a fore-sight established. There was a slight movement of the plumb-line, and its angular movements were measured several times. A mean position was determined, and from this the angle to the fore-sight observed. Before a base-line of sufficient length could be made five additional sights were necessary. This base-line, 590·25 links, was established by having bore-holes put in the roof, in which plugs were driven and staples fixed before final observations were taken. The distances were measured and booked in the usual manner. The party then returned to the surface by way of a second shaft near by, so as not to interfere with the plumb-line. The theodolite was set up at the surface a short distance from the shaft. The oscillations at the surface were very slight, and a fore-sight was fixed and the necessary observations and distances determined. The two shafts at the surface were connected by traversing in the ordinary manner, because the surface conditions, being level, favoured this method. Had the surface been of an undulating character a system of triangulation would have been the better method to adopt. A base-line, 1,140 links, was laid down as near the shaft as practicable, tiles were sunk into the ground to a depth of about 18 in., and a sufficient number of measurements taken so as to determine their position at some future date. It was from this base-line that the observations for determining the magnetic declination were taken. The traversing was continued, and when nearing the Margaret pit another base-line, 923 links, was laid down. The plumbing apparatus was now erected and wire suspended at the Margaret pit in exactly the same way as at the Derwentwater pit, traversing being carried on to the Margaret pit and the surface survey connected to the suspended wire. The party made their way underground by means of a day-drift travelling road to the seam at the shaft where operations were to be resumed. This was necessary so as not to interfere with the plumb-line in the shaft. The theodolite was set up underground, the wire observed, the angular movement measured, a mean position determined, and a fore-sight taken. A base-line, 405 links, was now established underground. The underground connection was made by connecting the two base-lines left near the two shafts. Several base-lines were established underground at convenient points so as to extend the survey into various districts.

The theodolite was only provided with a 2½ in. magnetic needle, and a miner's dial provided with a 6 in. magnetic needle was used to determine the magnetic bearings. The night following the surface survey the observations for the determination of magnetic declination by equal altitude of stars were carried out. The theodolite was set up at one end of the base and truly

centred, and a tripod set up at the other end, this also being truly centred and a lamp placed on the top. The lamp was used as a referring object. The zero of the graduated plate of the theodolite was made to coincide with this line, and the vernier plate released and allowed to rotate to any desired position. Three stars, each of the first magnitude, were selected. The first star was sighted and the horizontal and vertical angles noted. About 15 minutes later a second star was sighted, and in the same manner a third after another 15 minutes had elapsed. After crossing the meridian the last sighted star was the first to reach the altitude recorded on the west side of the meridian, and the horizontal angle was noted at the point of equal altitudes. The second star was then carefully followed until it corresponded with the altitude observed before the crossing, and again the horizontal angle noted. The same was obtained for the third star. Bisecting the horizontal angle passed through by each star the resultant line will be in the geographical meridian, and from this the azimuth of the base-line obtained. To find the magnetic bearing of this line the miner's dial was set up, clear of all magnetic attraction, about 50 yards from the theodolite, and a sight taken from the latter to the former, and vice versa. The dial was set up at other seven points around the theodolite. In this manner magnetic and azimuth bearings were obtained, and the mean of the difference between the two was the magnetic declination.

The clockwise angle between the various sights was measured and recorded as follows. After all the necessary adjustments of the instrument had been made the vernier A was brought near the zero of the graduated plate and clamped. The readings of both verniers A and B were noted. The telescope was then brought into perfect alignment with the back-sight and clamped. The vernier plate was then released and rotated clockwise until the fore-sight was in the field and accurately bisected by the hairs of the diaphragm. Both verniers were read. The above was repeated twice with vernier A near 60° and 120° of the graduated plate. The above method was continued throughout the survey, and after each sight had been taken a straight line was ranged out with lamps underground and poles at the surface and carefully measured, and a measurement checked in the opposite direction.

The magnetic bearing of the base at the surface having been determined, the remaining sights were calculated in relation to the magnetic meridian and the bearing and length of the tie-line obtained. The underground survey was calculated to an assumed meridian and the tie-line calculated. The difference between the assumed and the magnetic tie-lines was the bearing of the first sight underground. Knowing the magnetic bearing of the first sight, the remainder of the survey was calculated to the magnetic base. Twice in the underground survey observations were made to the miner's dial situate in an old roadway, and the two differed from the calculated by 6 minutes and 4 minutes respectively. This dial only read to three minutes. The plan was plotted by co-ordinates and compared with the working plan which has seen many years of service, and was found to be within the limits allowed.

Copper Losses in Slags.—In the *Engineering and Mining Journal* for December 4, F. E. Lathe, metallurgist to the British America Nickel Corporation, discusses the losses of copper in slags and the methods for determining the amounts of sulphide and oxide present in the slags. He also indicates lines of experiments for the reduction of losses. We quote this part of the paper herewith.

It is customary to place immediately below the blast furnace spout one large settler, the overflow from which goes to waste. Although the necessity for matte storage may require a settler of large size, it will often be found that two or more smaller ones in series will more effectively clean the slag; or the large settler may be followed by small ones. The fall of slag from one settler to another probably allows the escape of a certain amount of gas, which may have caused the flotation of matte particles. Such a treatment is especially desirable when analyses show that the percentage of sulphide copper in the slag is high, as may be true in matte concentration or in other cases with a high percentage of copper on the charge to the furnace.

If the oxidized copper in the slag be high, some may be reduced by the addition of coarse pyrite to the second-last settler of a series. This was done at the Grand Forks plant of the Granby company with some success. The coarse pyrite added settles to the matte, and the sulphur driven off by heat stirs up the slag and has an excellent chance to reduce oxides. The lower-grade matte produced in this way also has a tendency to cause the precipitation of dissolved sulphides, if present.

As regards reverberatories, owing to the presence of oxidized copper in the charge, and the comparatively neutral atmosphere in reverberatory smelting, the loss as oxide or silicate is likely to be high. To reduce this loss to a minimum there is no method more promising than that suggested some years ago by E. J. Carlyle. Mr. Carlyle thought that if a wall of refractory material were built across a reverberatory furnace near the skimming end, high enough to keep back the main body of matte, but low enough to allow the slag to flow over it, pyrite could be charged through the roof between this wall and the skimming door, thus bringing about a material reduction in the copper content of the slag. A separate tap-hole could be provided for the low-grade matte as well as a side door behind the dam for the removal of floaters. Such a practice would not involve radical changes in construction, and would appear to be of general application in reverberatory smelting.

If converter slag forms a large proportion of the charge, the sulphide content of the slag may increase. In such results, if the loss be due to sulphides floated by gas bubbles, the low-grade matte treatment may reduce magnetite introduced in the converter slag, and consequently bring down the sulphide loss, as well as reducing the oxides. To lower the sulphide content a succession of small settlers might also be effective, as suggested for blast-furnaces. In all such instances the amount of settling which can be done outside the furnace is dependent principally upon the degree to which the slag has been superheated before leaving the furnace.

Metallurgically speaking, it may be wasteful to pour converter slag into blast-furnace settlers, but one cannot say that such a practice is never justified. As in all other industries, smelting and converting are governed by commercial considerations, and these must be the deciding factors. This much may be said, however. In most plants possessing both converters and blast-furnaces, at least a part of the converter slag is re-smelted, and when this is done the slag to be poured into settlers should as far as possible be that produced in the early part of the blow, when oxidized copper is at a minimum. If the suggested modification of reverberatory furnaces should, upon trial, prove commercially successful, that would appear to be the logical outlet for whatever converter slag is not required for fluxing purposes.

Precipitation of Gold.—The October *Journal* of the Chemical, Metallurgical, & Mining Society of South Africa contains a paper by J. Hayward Johnson, entitled : "Notes on the Influence of Soluble Silica and Calcium Salts in the Process of Precipitation of Gold from Cyanide Solutions." As regards soluble silica the author quotes two cases : (1) A deposit found on the zinc in the sand solution precipitation boxes ; (2) a scum found at the head and between compartments of sand solution precipitation boxes. The sample (1) of deposit and metallic zinc received was stirred with water and the deposit decanted away from the metal until as much zinc as possible was eliminated. The purified deposit was dried and analysed with following results :

	%
Calcium Oxide	26·4
Carbon Dioxide	18·0
Zinc Oxide	9·0
Sand, etc., insoluble	0·8
Combined Water	18·0
Soluble Silica	22·8
Sulphur as Sulphate	0·7
Sulphur as Sulphide	1·0
Magnesium Oxide	0·9
Iron Oxide	1·1
Gold and Silver	0·22
Organic Matter, Lead, etc.	Traces.

The deposit was therefore practically composed of calcium carbonate and gelatinous silica containing water. The mixture was very readily soluble in dilute acids, but if the solution was heated, neutralized, etc., the colloidal silica at once assumed the gelatinous form and was deposited. The silica formed an impermeable coating on the zinc and prevented precipitation. If the solutions entering the boxes were perfectly clear, it is apparent that the silica must exist in the colloidal sol form and be deposited on the zinc in the gel form by chemical or galvanic disturbance.

(2) The scum from the precipitation boxes was practically the same as that found on the zinc shavings, consisting of calcium carbonate and colloidal silica mixed with a little wax. The latter was probably derived from candle grease and is the cause of the flotation of the scum.

The turbidity of the slime solution after 24 to 48 hours' settlement (KCy 0·005% CaO 0·008%) was due to silica in a very fine state of division (presumably colloidal suspensoids) which was not removed by the sand clarifiers. This turbidity remained in the plant for a period of about seven days, but did not show itself in every charge treated during that period.

The make-up water used in the reduction plant was obtained from a dam which received part of its water from a valley into which the drainage from several old sumps, slime dams, and the compound was delivered. The ignited solids contained in this water were as follows :

	Parts per 100,000.
Silica and insoluble	2·3
Oxides of iron and alumina	2·3
Oxide of calcium	13·0
Oxide of nickel	2·7
Oxide of magnesium	3·6

Two samples of so-called white precipitate, one from the East Rand and one from West Rand, showed on examination that they carried 37·95% and 38·75% silica, respectively, which was found in a very fine state of division, almost gelatinous.

The foregoing instances fairly demonstrate that colloidal silica has quite a considerable effect on precipitation. In connection with all these cases, considerable trouble was experienced in the filter press, the silica forming on the filter papers in a gelatinous film, almost impervious to water, and causing a rapid rise in pressure on the press.

Excessively burnt lime, when the limestone carries an amount of silica, is also responsible for the introduction of soluble silica into the solution.

The excess alkalinity in the solution circuit is well known to have a detrimental effect on precipitation, and this excess is sometimes caused by the slow solubility of the lime.

The deleterious influence of the sulphates and of carbonate of lime is no doubt due to the formation of protective coatings on the zinc. Regarding the sulphates, the trouble does not develop apparently until the point of saturation is reached (256 parts per 100,000), when it becomes rapidly acute. The use of the condenser circuit of the steam plant as make-up water, though the circuit water is valuable on account of its available heat during the winter months, is, owing to its prior concentration, very liable to develop this point of saturation, in conjunction with the neutralized acid salts of the ore. With the large amount of reclamation work being carried out on many mines and consequent treatment of partly oxidized ores, the amount of calcium sulphate in solution tends to increase, and during the long winter drought usually develops trouble.

A Cyanide Clean-up Problem.—In the *Monthly Journal* of the Chamber of Mines of West Australia for September, W. B. Chomley gives an account of difficulties encountered in the cyanide clean-up at the Oroya Black Range gold mine and the method of surmounting them. The difficulties arose from the presence of copper in the ores.

It had been the custom to do the smelting in a tilting furnace, and to refine the resulting bullion by the well-known method of stirring sulphur into it while molten. The practice of smelting with an oxidizing flux in a clay-lined crucible had been tried and had proved successful as far as the grade of bullion was concerned ; but it had been abandoned as being too tedious, owing to the low gold contents of the slime. The clarifying arrangements were not equal to the capacity of the rest of the cyanide plant ; consequently the solution coming to the extractor boxes was frequently cloudy. This accounted for the large bulk of poor slime which had to be handled at each clean-up. Much might be said as to the comparative merits and disadvantages of these two methods of gold-refining, but it is only necessary here to remark that by the use of the sulphur method, even after all the gold in the matte and ashes has been taken into account, a slight deficiency has been observed. This loss is difficult to explain, but is easy to estimate ; while on the other hand, that which occurs while charging an open pot in a wind furnace is quite simple to understand, but almost impossible to estimate.

Clay-lined pots had been tried in the tilt furnace, but they were not a success, for as soon as a crack or flaw developed in the lining, which in these pots is not removable, the carbonaceous material composing the outer shell was subjected to the oxidizing action of the whole of the charge, usually with disastrous results, as these cracks generally occurred at or below the level of the molten metal.

In the early life of the mine, the copper had been an unimportant factor, but as the upper levels became depleted and the proportion of ore drawn from the sulphide zone increased, the copper contents of the cyanide bullion did likewise, until a stage was reached when it amounted to over 50% of the total. This increase in the copper in the ore had no deleterious effect upon the recoveries, as the undissolved gold in the residue seldom exceeded two shillings in either the leaching or agitation plants. Precipitation in the zinc-boxes sometimes gave trouble, but although it was demonstrated that copper-coated zinc was a less active precipitant than

the clean shavings the fact that while the presence of copper was constant, these periods of bad precipitation were intermittent, indicated that the seat of the trouble lay elsewhere.

Of the many possible causes that were considered in the search for an explanation for these periods of partial breakdown in the precipitation, that connected with varying ratio of zinc cyanide to free KCN seemed to be the most probable. The physical condition of the solution, that is, whether it was clear or cloudy, seemed to have no direct connection with it. It was always noticed that the new zinc in the lower compartments of the extractor boxes quickly became coated with a film of copper and that as it was moved up toward the head of the box to take the place of that which had been consumed, the copper was gradually replaced by gold, and that short zinc in the top compartment was practically copper free. Obviously a simple way of obtaining bullion free from this base would have been to take out only the short zinc and to leave the remainder for the next clean-up, but unfortunately economic reasons demanded quite the opposite course.

The chief trouble, and the one with which this paper is mainly concerned, arose through the corrosive action of the roasted slime, or rather the oxidized copper, upon the plumbago crucibles. The flux which had been found most suitable was approximately as follows: roasted slime 100 parts, borax glass 40, silica 5. It will be noticed that the percentage of silica here is very low; but it must be remembered that the slime itself contained some gangue material which had escaped the clarifier. Sometimes it was necessary to leave out the silica and add sodium bicarbonate in order to obtain a fluid slag. An over-silicious slag was really worse on the pot than a basic one, as the time and temperature required for fusion were increased. It was seldom at that time that a pot lasted out one full clean-up, and it often happened that one ran through during the first charge, and the amount of work and trouble that this entailed was considerable.

At that time the supply of crucibles, like all other mining stores, was very uncertain, but it was imperative that some means should be found to stop this destruction of valuable and perhaps non-replaceable articles. Several attempts were made to remove the copper from the slime prior to smelting. On an experimental scale this was quite simple, but many difficulties arose when it came to put any of these methods into practice. It was found that boiling the raw slime in concentrated sulphuric acid would accomplish the desired purpose, but this was quite impracticable with the plant available. Dilute nitric acid was tried, but although it attacked the copper, owing to the presence of much chlorides in the water supply, an appreciable amount of gold went into solution, which discouraged further investigation in that direction. The copper oxide was very soluble in dilute sulphuric acid, and a clean-up carried out on these lines produced bullion almost free from base, and also reduced the work of smelting to a minimum; but it was found to be absolutely necessary to clear the slime before bringing it into contact with the liquid, otherwise great loss by dusting would take place, and in dealing with a large quantity of material, this required more time than circumstances allowed. Another serious objection to this second acid treatment was the extra handling involved.

As a return to the original method of smelting with the certainty of having to refine the bullion seemed inevitable, the matter was viewed in a different light. As the whole of the trouble had been caused by the copper, which, after being oxidized by the roast, would be reduced back to metallic state at the expense of the pot, the question which presented itself was "Why roast at all?" It was realized that some of the zinc, which otherwise would have been roasted off, would find its way into the bullion, but it seemed safe to assume that in the presence of so much copper this would be a negligible quantity. Accordingly a sample was dried at a low temperature, fluxed on its calculated roasted weight, and fused in a small plumbago crucible. The result was encouraging, but the dried slime proved very dusty and more difficult to handle than that which had been roasted thoroughly, so trials were made on damp slime, with equally satisfactory results. Some misgivings were felt before attempting to smelt wet gold-slime on a working scale, and the first charge was very carefully fed into a barely warm pot after a layer of borax had been first sprinkled over the bottom. These precautions were subsequently found to be unnecessary, and wet slime would be fed into a red hot pot without any ill effect. It is not known exactly what percentage of moisture the slime held, but it had only been dried on a vacuum filter and was distinctly wet before it was fluxed. No great evolution of gas or steam took place during fusion, but the charge just sank quietly down and was periodically topped up. A good deal of the surplus moisture was taken up by the borax glass in the flux, which caused the whole to set into a fairly dry-looking mass. A section of the charge after it had been going for some time would have disclosed a gradual transition from the wet slime on top, through a layer of what looked like ordinary roasted slime, then a zone of slag with the molten metal beneath. The resulting bullion was not appreciably worse than formerly, and there was no noticeable action on the pot at all. The actual time taken in smelting was somewhat longer; but this was counterbalanced by that saved by cutting out the roasting. The manual labour was reduced, which was a consideration during the hot months.

After the first pot had been in use for three months it was removed as a precautionary measure. Upon examination it was found to be quite sound and looked good enough to have lasted as long again. This effectually put an end to those mishaps which had unfortunately become the rule rather than the exception, and the output was not again delayed while the contents of the ashpit and furnace were being re-smelted. It was really the smelting of this mixture that first suggested the course ultimately adopted, as it was noticed that in these cases the pot was not attacked to the same extent as usual. The cause of this was soon traced to the reducing action of the small pieces of coke in the charge which protected the less easily oxidized graphite in the crucible.

It may be mentioned that the author has subsequently made trials of this method on other mines where the same circumstances did not prevail, and as might be expected, in the absence of any other base in large quantities, the remaining zinc was sufficient to spoil what would otherwise have been fair grade bullion, and the process was not applicable, but under the conditions described it can be claimed that it was a decided success.

SHORT NOTICES

Stope-Filling.—The November *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper by Walter Herd on the proposed application of hydraulic stowing to the submarine coal workings at Sydney, Nova Scotia.

Stope-Filling.—At the November meeting of the Junior Institution of Engineers, R. H. Squire read a paper on hydraulic sand-packing as practised in Indian collieries.

Electric Power in Mines.—*Engineering* for December 17 contains a paper describing the electric winding, hauling, and ventilating plant at the Easington Colliery, Durham. The electric plant was supplied by the General Electric Co., Ltd.

Compressed Air.—At the December meeting of the North of England Institute of Mining and Mechanical Engineers, J. T. Pringle read a paper on the production and transmission of compressed air in mines.

Francois Cementation Process.—At the meeting of the South Wales Institute of Engineers held at Cardiff on December 16, H. Standish Ball read a paper on the Francois system of cementation for stopping the flow of water in shafts and drifts.

Surveying.—The *Colliery Guardian* for December 17 prints a paper read at the South Wales branch of the Institute of Mine Surveyors of Great Britain on the line of collimation in dumpy levels, etc.

Electrolytic Zinc.—*Mining and Metallurgy* for December contains an abstract of a paper on the electrolytic zinc plant at Anaconda, by F. Laist, F. F. Frick, J. O. Elton, and R. B. Caples, to be read at the February meeting of the American Institute of Mining and Metallurgical Engineers.

Electrolytic Zinc.—The *Mining and Scientific Press* for December 4 contains a paper by H. R. Hanley on the electrolytic method of producing zinc. The author's experience was at Bully Hill, California.

Electrolytic Zinc.—In the *Engineering and Mining Journal* for December 11, G. C. Heikes describes the electrolytic zinc plant of the Judge Mining & Smelting Co., Park City, Utah.

Melbourne University.—In the *Industrial Australian and Mining Standard* for October 14, A. J. Higgin describes the metallurgical department of Melbourne University.

Metallurgical Laboratory.—In the *Engineering and Mining Journal* for November 20, H. O. Hammond describes the laboratory attached to the smelting plant of the United Verde Extension copper mine, Arizona.

Gold-Mining in the Philippines.—In the *Mining and Scientific Press* for December 4, C. M. Eye and M. F. Dodd commence an article on metallurgical practice at the Benguet Consolidated gold mine in the Philippine Islands.

Atmospheric Impurities.—In *Chemical and Metallurgical Engineering* for December 8, Osborn Monnett commences an article on the determination of atmospheric impurities, with particular reference to the atmosphere around smelting works, as at Salt Lake City.

Phosphorus from Rock Phosphate.—In *Chemical and Metallurgical Engineering* for December 1, W. H. Waggaman and T. B. Turley describe the production of phosphoric acid from rock phosphate by smelting with sand and coke in a furnace fired with oil fuel and electrostatically precipitating the phosphoric acid evolved.

Mandy Mine.—The November *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper by G. R. Bancroft on the mining operations at Mandy mine in The Pas district, Manitoba.

Manitoba Geology.—The November *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper by R. J. Colony on the occurrence of norite, similar to that at Sudbury, at a point twenty miles east of the southern end of Lake Winnipeg.

Bolivian Tin Mines.—In the *Engineering and Mining Journal* for November 20, J. T. Singewald describes the tin deposits in the Quimsa Cruz mountains, Bolivia.

Spitsbergen.—At the December meeting of the Mining Institute of Scotland, H. M. Cadell read a paper on coal mining in Spitsbergen.

Kent Coal.—In the *Iron and Coal Trades Review* for December 10, H. A. Baker writes on the structural features of the Kent coalfield.

Oil in Palestine.—At the meeting of the Institution of Petroleum Technologists held on December 14, Paul H. Mangin read a paper on boring in Palestine.

South African Diamonds.—At a meeting of the Royal Society of Arts held on January 3, F. C. Cornell read a paper on the alluvial diamondiferous deposits of South-West Africa.

British Columbian Topography. — In the *Geographical Journal* for January, Howard Palmer describes the topography of the region north of Revelstoke, British Columbia, including the Gold Range and the northern Selkirk mountains, a hitherto unmapped territory.

RECENT PATENTS PUBLISHED.

13,536 of 1920 (154,512). DORR CO., Denver. An improved classifier.

14,711 of 1920 (152,939). R. H. HARRIS, Seven Sisters, Glamorgan. Improvements in the inventor's electric detonators.

16,525 of 1920 (145,442). FRIED. KRUPP GRUSONWERK, Magdeburg-Buckau, Germany. Improved magnetic separator.

18,032 of 1920 (145,734). FRIED. KRUPP GRUSONWERK, Magdeburg-Buckau, Germany. Device for closing the tap-hole in smelting furnaces.

20,656 of 1920 (148,818). H. STEHMANN, Berlin. Blast-proof closing of discharging devices for blast-furnaces.

27,659 of 1920 (152,990). TH. GOLDSCHMIDT, Essen, Germany. Method of obtaining carbon-free ferro-chromium from chrome-iron ores by the alumino-thermic process.

NEW BOOKS, PAMPHLETS, Etc.

☛ Copies of the books, etc., mentioned below can be obtained through the Technical Bookshop of *The Mining Magazine*, 724, Salisbury House, London Wall, E.C.2.

The Oil-Shale Industry. By VICTOR C. ALDERSON. Cloth, octavo, 180 pages, illustrated. Price 26s. New York: Frederick A. Stokes Company.

Hitherto when it has been necessary to get together some general information concerning the technology of oil-shale, the amount of reference work needed in elucidating the really fundamental data has proved to be no small task, and if for no other reason than that, Dr. Alderson is to be congratulated on the production of the present comprehensive volume. As will be gathered from the bibliography included at the end of the book, most of our knowledge of the subject is scattered over a wide field of literature, some of it easy, but most of it difficult, of access to the average person outside a technical or scientific institution. One result of this is that the prevalent ideas concerning the oil-shale industry are somewhat confused and even conflicting, and we

therefore welcome the appearance of a volume which summarizes all the information thus far accumulated in so satisfactory a manner.

The book is essentially economic, and does not attempt to deal with the many vexed geological and chemical questions as yet remaining unsolved with regard to shale oil; probably this is a good feature, since in the present state of our knowledge little value would accrue to such considerations unless they were of a very exhaustive character. With the growth of the industry both at home and abroad research is bound to receive a further stimulus, and much that is at the moment imperfectly understood will doubtless be made clear in the light of new facts and hypotheses thus advanced. To this end, and as an offset against the gradually declining production of crude oil, the author's main plea throughout the work is the immediate development of the world's oil-shale resources, and in this he has the fullest support of all far-sighted men of to day.

We in this country are constantly hearing of the "vast mountains of oil-shale" hitherto untouched in America, and possibly we may regard such a statement as a piece of pardonable exaggeration on the part of our enthusiastic friends in the States. But Dr. Alderson shows in a most convincing manner that far from being an exaggeration it is possibly but a modest computation of the resources of that country. We read (page 29) that in the Utah portion of the Uintah basin alone there are 40,000,000,000 tons of shale which, yielding a barrel of oil to the ton under normal working conditions, will require over 500 years for their exhaustion; similarly in Colorado there would seem to be at least 800 years' supply! Such estimates as these, which omit all consideration of oil-shale deposits elsewhere, both in America and other countries, are sufficient in themselves to make us wonder why such valuable resources of oil fuel should remain comparatively undeveloped until now, and we are driven to seek an explanation in the study of the many commercial aspects of the problem. Of these, one factor stands out very clearly, quite apart from prevalent economic conditions, and that is the general crudeness of present methods of shale-refining. It is well known that no one method of retorting, for example, will suit all facies of shale; a process well adapted for the treatment of the Scottish shale may be quite inapplicable in the States or in other parts of the world, where the nature of the shales, climatic conditions, and economic criteria are all varying factors, and where the difficulties of initiating satisfactory commercial processes to meet local requirements are extremely acute. Such obstacles can only be overcome by much detailed experimental work, work which we are glad to see is at last claiming the attention of experts both in this country and abroad.

The author deals at some length with the several processes of refining at present employed, and he supplies some valuable information from the results of much experimental work carried out at the Colorado School of Mines, of which he is himself the president. In this country similar work has been done and is in progress in the Oil Technology Department of the Royal School of Mines, and we take this opportunity of framing a few criticisms of the method of shale distillation carried out at the former school, and described in detail in the present volume on page 94 et seq.

(1) The cast-iron retort or pot-still described by Dr. Alderson might with advantage be replaced by an iron tube, since uniform heating of the shale is thus much more rapidly obtained.

(2) When carrying out the distillation with steam, there is a danger in using the pot-still, since the steam will tend to take the easiest channel through the material without passing uniformly through the shale; this danger is minimized with a tube retort, especially if the latter be narrow, say 2½ in. internal diameter.

(3) There is also a danger of some of the oil condensing on the cooler upper surface of the pot-still, and in the vertical portion of the delivery tube, thus dropping back on to the hot shale and becoming decomposed, a possibility largely eliminated in the tube retort.

(4) More rapid methods of estimating the yield of ammonium sulphate can be employed than that described by the author. If the ammonia water is not too strongly coloured, a known excess of normal $NaOH$ solution may be added; the oily bases thus liberated may be extracted by shaking with petroleum ether, when by titrating back the aqueous layer with standard acid, the amount of ammonia present in the liquor may be easily determined. Where the ammoniacal liquor is too strongly coloured to make this method possible, the yield of sulphate may be determined by rendering it strongly alkaline with $NaOH$ and distilling off the ammonia into standard sulphuric acid. The oil must of course be separated from the liquor in the first place.

The book is markedly free from technical and literary inaccuracies, and is in itself a tribute to the patient and thorough work which the author has been and is doing; his inquiries made personally in this country during the early summer months of last year with reference to the oil-shale industry in England and Scotland, and reported at some length in the October issue of the Quarterly of the Colorado School of Mines, clearly show the broadmindedness and sincerity of the effort which he and his pupils are making in an organized endeavour to establish the foundations of a far greater oil-shale industry than the world has yet appreciated.

H. B. MILNER.

The Sunset-Midway Oilfield, California. By R. W. PACK. United States Geological Survey, Professional Paper 116.

This memoir deals with the geology and technology of the oil resources of an area situated at the southern end of the San Joaquin valley, Kern County, California, and is yet another example of the high standard of excellence attained by American publications of this nature. It constitutes Part I. of the Official Report on the Sunset-Midway field, and besides giving a thorough account of the occurrence of petroleum there, it contains some most valuable information on oil accumulation which, by reason of its wider application, repays careful study.

The author first treats of the stratigraphy of the district, which consists essentially of an enormous mass of Tertiary sediments reposing unconformably on a complex of granitoid rocks with associated metamorphics, forming part of the great batholith of the Sierra Nevada. These sediments have an estimated thickness of 18,000 ft., and though not expressive of continuous deposition, they range in age from Eocene to Pliocene, with but few important stratigraphical breaks in the succession. Of these deposits the central Miocene diatomaceous formation is both geologically and economically the most characteristic, and is referred to here as the Maricopa Shale series, the lower part of which is equivalent to the younger beds of the better known Monterey group of this region. The oil is regarded as indigenous to this series, which has a thickness here of nearly 5,000 ft., and most of the productive horizons of this field are located in and about these shales.

The geological structure of the area is by no means simple. The accumulation of oil has apparently been controlled by a series of folding movements along a line trending W.N.W.-E.S.E., a direction somewhat

oblique to the strike of the main coastal range. This folding has produced a series of anticlines and synclines, in places closely packed together, with a certain amount of concomitant faulting, especially in the south, in the San Emigdio Mountains, where the main structure lines are trending practically E.–W. Most of the productive fields of the region to the west of the San Joaquin valley, embracing the Sunset-Midway district, are situated near the axes of these anticlinals.

With regard to actual production, up to January 1, 1918, 2,827,900,000 barrels of oil had been obtained from over 2,000 wells drilled; from the statistical details given by Arnold in the "Manual for the Oil and Gas Industry," pp. 148–152, it is evident that the future prospects of the Sunset-Midway field are exceedingly good, such being the impression also conveyed from a study of this memoir and of the excellent maps included.

H. B. MILNER.

The Mineral Industry: Its Statistics, Technology, and Trade during 1919, Vol. xxviii. Edited by G. A. Roush and Allison Butts. Cloth, octavo, 902 pages. Price £2. 15s. 0d. New York and London: McGraw-Hill Book Company.

Ontario Department of Mines 29th Annual Report. Part IV: Kirkland Lake Gold Area, by A. G. Burrows and P. E. Hopkins.

Ontario Department of Mines 29th Annual Report. Part III: Ben Nevis Gold Area, by C. W. Knight; West Shiningtree Gold Area, by P. E. Hopkins; Matachewan Gold Area, by A. G. Burrows; Argonaut Gold Mine, by C. W. Knight; Gowganda Silver Area, by A. G. Burrows.

Coal in Great Britain: The Composition, Structure, and Resources of the Coalfields, Visible and Concealed, of Great Britain. By Dr. WALCOT GIBSON. Cloth, octavo, 320 pages, illustrated. Price 21s. net. London. Edward Arnold.

COMPANY REPORTS

Dolcoath Mine.—The report of this Cornish tin-mining company for the six months ended June 30 last shows that 30,052 tons of ore was treated, yielding 338½ tons of tin concentrate, or 25·2 lb. per ton. This was sold for £70,751, and in addition £1,918 was received from the sale of crude arsenic. Other items brought the total receipts to £74,732, against which there was an outgoing of £86,006, including £3,213 paid as debenture interest. The loss for the half-year was £11,275. Since the end of the half-year the bottom workings have been abandoned, and operations have been continued on a reduced scale. The proposal to explore to the north is given in detail elsewhere in this issue.

Sub-Nigel.—This company was formed in 1895 to acquire property on the dip of the Nigel gold mine in the Heidelberg district of the Far East Rand. In 1909 the adjoining property of the Nigel Deep was absorbed. More recently property on the dip in the Grootfontein has been acquired, and an extensive scheme of development inaugurated. The control is with the Consolidated Gold Fields of South Africa. The report for the year ended June 30 last shows that 117,304 tons of ore was sent to the mill, where 38,911 oz. gold was extracted by amalgamation and 33,862 oz. by cyaniding, being a total of 72,773 oz., or 12·33 dwt. per ton. The gold was sold for £384,365, of which £76,311 represented premium. The value of the yield per ton was 65s. 1d., or excluding premium 52s. 2d. The working cost was £253,636, or 42s. 11d. per ton, leaving a profit of £130,729, or 22s. 2d. per ton, out of which £70,000 was distributed as dividend, being at the rate of 10%. The developments have not maintained the ore reserve, which stands at 284,000 tons averaging 10 dwt. The new vertical shaft reached the reef at a depth of 2,379 ft. in November, 1919, and connection has been made with the 17th and 21st levels. Since the close of the company's financial year, developments on the 21st level have disclosed a number of runs of profitable ore.

Knights Deep.—This company was formed in 1895 to acquire deep-level claims in the middle-east Rand, and milling commenced in 1903. The control is with the Consolidated Gold Fields of South Africa. From 1905 to 1917 satisfactory dividends were paid regularly. In September, 1920, the mill was destroyed by fire. Under the conditions now ruling at this low-grade mine, it was impossible to rebuild the mill, so the company is to go into liquidation. The report for the year ended July 31 last shows that 1,070,200 tons of ore was raised and milled, for a yield of 193,881 oz. This gold was sold for £1,049,480, of which £224,236 represented premium. The income per ton milled was 19s. 7d., of which 4s. 2d. was premium. The working expenses were £940,965, or 17s. 7d. per ton, leaving a working profit of £108,514, or 2s. per ton. A dividend of 3¾% was paid in January, 1920, absorbing £27,882. The ore reserve was estimated on July 31 at 727,000 tons, averaging 4·8 dwt. over 65 in.

Luipaard's Vlei Estate & Gold.—This company was formed in 1888 by the Consolidated Gold Fields to work a gold-mining property in the far west Rand. Milling was started in 1898, but was suspended on the outbreak of the Boer war, and was not resumed until 1906. In 1909 the adjoining Windsor mine was absorbed. In 1912 the control was acquired by L. Ehrlich & Co. The property consists of four sections, two on the Main Reef Series, and two on the Battery Reef to the south. Small dividends were paid in 1908, 1909, and 1916. The report for the year ended June 30 last shows that 226,985 tons of ore averaging 4·99 dwt. per ton was sent to the mill, where 52,523 oz. of gold was extracted by amalgamation and cyaniding, being a yield of 4·628 dwt. per ton. The amount realized, including premium, was £276,026, while the working cost was £247,906, and the item for development redemption was £34,047. Thus the total working cost was £281,954, and the adverse balance for the year £5,928. A shortage of native labour and a fall in the stoping width of the reefs had a very serious effect on the output and revenue, and at the same time the costs went up 3s. 6d. as compared with the previous year. An advance in the gold premium came to the rescue, however, and obviated the contemplated stoppage of operations. It is now intended to resume development directly a supply of natives can be obtained. The reserve stands at 701,847 tons averaging 5·2 dwt., together with 84,564 tons partly developed expected to average 5·71 dwt. per ton.

Witbank Colliery.—This company was formed in 1896 to acquire coal lands in the Middelburg district of the Transvaal, about 90 miles east of Johannesburg. The control was with Neumann's, but is now with the Central Mining & Investment. The report for the year ended June 30 last shows that sales amounted to 995,589 tons, of which 550,818 tons came from the Witbank mine and 444,771 tons from the Uitspan mine. The total was 127,734 tons higher than that for the previous year, and was the highest recorded in the history of the company. The profit for the year was £96,750, out of which £61,250 was distributed as dividend. During the year, £140,000 of the accumulated profit, used in the business, was capitalized, and 140,000 shares were distributed as a bonus to shareholders. The capital of the company was thus raised from £210,000 to £350,000.

Taquah Mining & Exploration.—This company was formed in 1888 as the Taquah & Abosso Gold Mining Co., to acquire gold-mining properties in Gold Coast Colony, West Africa. In 1901 the company was split, the Abosso mine being transferred to a subsidiary company. The report for the year ended June 30 last shows that 53,844 tons of ore was sent to the mill, and that the total yield of gold was 32,907 oz. The par value of the gold was £139,550, and the premium brought the total receipts up to £173,879. The working cost was £109,544, and allowance for depreciation £27,782, while £13,317 was received as dividends and profits on sale of shares. The net profit was £51,129, out of which £48,434 was distributed as dividend, being at the rate of 12½%. The ore reserve was estimated on June 30 at 182,226 tons averaging 52s. 6d. par value. Labour shortage has interfered with development. The lode turns upward at the 14th level of the internal shaft. This has been followed for 250 ft., and its further continuance is now being tested.

Abosso Gold.—This company is a subsidiary of the Taquah, particulars of which are given in the preceding paragraph. The report for the year ended June 30 last shows that 82,588 tons of ore was treated, averaging 37s. 8d. in gold per ton par value. The yield of gold was 33,555 oz., worth £142,310 par value, or with the premium £177,735. The net profit was £50,039, out of which £50,000 was distributed as dividend, being at the rate of 12½%. Developments continue to be satisfactory, and the reserve at June 30 was calculated at 300,000 tons averaging 34s. 6d. par value. The shortage of available labour is a serious question at present. During the year the property of the Wassau (Gold Coast) Mining Co. has been purchased for £20,000. This property consists of mining areas on the dip of the Abosso and of timber concessions near by.

Prestea Block A.—The report of this company, operating a gold mine in West Africa, for the year 1919, just published, shows that 181,398 tons of ore was milled for a yield of gold selling for £330,090, of which £29,222 came from premium. The yield per ton was 36s. 4d. The working cost was £297,657, or 32s. 9d. per ton, and allowance for depreciation £25,605. The ore reserve at December 31 was estimated at 317,350 tons averaging 38s. 8d. per ton, as compared with 469,645 tons at the end of 1918. The newly discovered ore-body north of Prestea shaft is giving good results, and the average assay-value is higher than that of the ore reserve. The length of the pay-shoot on this ore body is greater on the 12th than on the 11th level, but on the 13th level the results are not so satisfactory. Owing to the bad nature of the ground in Prestea shaft, the development of the lower levels is to be done by an auxiliary internal shaft. The mine has suffered greatly by shortage of labour, as have all other mines in West Africa.

Northern Nigeria (Bauchi) Tin Mines.—This company was formed in 1910 to acquire alluvial tin ground at N'Gel in Nigeria from the Anglo-Continental Mines Co. An account of the property was given in the MAGAZINE for February, 1918, and in March, 1920, particulars were given of the hydro-electric installation in course of erection. The report for the year ended June 30 last shows that the output of tin concentrate was 465 tons, an increase of 100 tons as compared with the previous year. Of the total, 268 tons came from the Gona section. The profit was £14,150, out of which £10,039 was distributed as dividend on the preference shares. Additional properties and licences have been acquired, and much exploratory work has already been done. Altogether ground estimated to contain 1,876 tons has been proved, bringing the total contents of the proved ground to 9,797 tons. The construction of the new plant is progressing, but owing to increases in the price of materials the cost will be much greater than originally contemplated, and a further £125,000 will be required. Negotiations are at present in hand for the raising of this amount.

Jantar Nigeria.—This company was formed in 1912 to work alluvial tin ground near Naraguta, Nigeria. The report for the year ended September 30 shows that 143 tons of tin concentrate was extracted, as compared with 110 tons and 166 tons during the two preceding years. In addition to the income from sales there is an item in the accounts of £4,100 as returned excess profits duty, which had the effect of converting a deficit on working into a profit balance of £838. Owing to labour shortage it has been impossible to work the new properties recently acquired. As recorded last month, the company is being amalgamated with the Kuru South and the Kuru Syndicate.

Dua (Nigeria) Tin Fields.—This company was formed in 1902 to acquire mining rights in Bauchi Province, Nigeria. In 1907 it acquired the properties on the Jarawa, previously owned by Mertens, of Hamburg, and also properties on the Juga river at Sutumi. J. H. Cordner-James is the chairman. The report for the year ended June 30 shows that the output of tin concentrate was 46½ tons. The receipts were £10,787, and the expenditure £15,260, leaving an adverse balance of £4,473. The Sutumi property has proved to be a great disappointment. Parts of the Jarawa property also have given similar adverse results, while the parts containing tin would require considerable expense for pumps to give an adequate water supply. Under existing conditions the directors do not consider such expenditure warranted.

Menzies Consolidated Gold Mines.—This company was formed by C. Williamson Milne in 1895 to acquire gold-mining properties at Menzies, West Australia. R. Goninon is manager. The capital is £224,015, and the only dividends paid were distributed for the four years 1914 to 1917, when 2½% per year was paid. The report for the year ended July 31 shows that 19,909 tons of ore was milled, yielding 10,080 oz. of gold bullion, by amalgamation, cyaniding, and concentration. This gold was sold for £52,332, of which £12,927 represented premium. The net profit was £3,231, which was carried forward. Development has given unfavourable results during the year, and the ore reserve has declined. The shaft has been sunk to 1,933 ft., and a 19th level is to be opened. The future of the mine will depend on the results obtained.

Yuanmi Gold Mines.—This company has been working the Yuanmi gold mine in the East Murchison goldfield, West Australia, since 1911. Dividends were paid in 1913 and 1914, but afterward developments gave poor results. A year ago conditions became more hopeful. In order to raise additional capital, 500,000 preference shares at 2s. each were created, and of these 220,000 have been issued so far. The report for the year ended June 30 last shows that labour conditions have prevented any comprehensive scheme of development being undertaken. In fact the shortage was such that the treatment operations were suspended for several periods totalling three months. Owing to faults and dykes the ground is not easy to prospect. During the year 14,922 tons of ore was treated, yielding gold which sold for £57,920. The expenses were greater than the income by £2,013.

Sulphide Corporation.—This company owns the Central lead-zinc-silver mine at Broken Hill, a lead smelter at Cockle Creek, near Newcastle, New South

Wales and a zinc smelter at Seaton Carew, County Durham. The mine was idle during the year ended June 30 last covered by the report now issued. On the exhaustion of stocks, the Cockle Creek smelter was closed at the end of 1919. During the six months it was working, 15,885 tons of mine and custom ore was smelted for a production of 3,849 tons of lead bullion containing 5,802 oz. of gold and 503,493 oz. silver. At the refinery there was produced 3,597 tons of soft lead, 207 tons of antimonial lead, 8,333 oz. gold, and 664,407 oz. silver. At the sulphuric acid plant the production was 13,[illegible] tons, and at the superphosphate plant 17,398 tons. The Central zinc works at Seaton Carew was occupied in treating zinc material that had been purchased by the British Government, including some from Australia. The amount of roasted concentrate smelted was 8,362 tons, from which was produced 2,817 tons of spelter, 13 tons of zinc dust, and 17 tons of lead. The residues, 6,316 tons, were too low in lead and silver to warrant treatment, with the exception of 336 tons, which was concentrated for a yield of 67 tons of leady material. The company's accounts show a balance of profit of £32,394, but it was not possible to distribute a dividend.

Fremantle Trading.—This company was formed as the Western Australian Smelting Co. in 1897 to erect a smelter and to work lead mines in the Northampton district of West Australia. A description of the property was published in the MAGAZINE for March, 1919. The mines were reopened in February, 1920. The report for the year ended July 31 shows that at the Baddera mine 2,978 tons of ore yielded 506 tons of concentrate averaging 72% lead; at Narra Tarra, 8,406 tons of ore yielded 975 tons averaging 70·9%; at Wheal Ellen, 208 tons of ore yielded 44 tons averaging 71·6%. At the smelting works 1,134 tons of ore and concentrate was treated for a yield of 579·6 tons of soft lead, which was sold at an average price of £40. 16s. per ton. The accounts show a profit of £2,378, which was carried forward. The labour position and the low price of lead make it uncertain how long operations can be continued.

Chinese Engineering & Mining. — This company was formed in 1900 to acquire coal mines at Kaiping, in the State of Chi-li, north China. It was reconstructed in 1912 in order to effect a working arrangement with the Lanchow company, a Chinese-owned company operating in the same neighbourhood. The businesses of these two companies are now controlled by the Kailan Mining Administration. The report for the year ended June 30 last shows that the sales effected by this Administration during the year were 4,010,980 tons of coal, an increase of 882,303 tons as compared with the previous year, and the net profit was $8,917,456, of which the Chinese Engineering & Mining Co.'s share was $4,581,804. The net profit of the company was £1,112,412. Out of this, £524,702 has been placed to reserve for excess profits duty, and £300,000 has been distributed as dividend, being at the rate of 30%. It is proposed to capitalize £400,000 of the accumulated profits. For this purpose the nominal capital is to be increased from £1,000,000 to £2,000,000, and after the 400,000 new shares are issued, 600,000 will be available for issue whenever desirable. The reason for this provision of further capital arises out of a project for establishing an iron industry. The company and the Lanchow company have acquired an iron ore deposit on the Yangtse River, reported by Frank Merricks to contain 4,000,000 tons of high-grade ore. It is proposed to build a smelter at the port of Chinwangtao from plans prepared by F. W. Harbord.

Cape Copper.—This company was formed in 1863 to work copper mines in Little Namaqualand, Cape Province. The ore and matte were brought to Briton-ferry, South Wales. More recently copper mines in Rakha Hills, Chota Nagpur, India, have been developed. The report for the year ended August 31 shows that mining operations are still in abeyance at the Cape, having been discontinued in May, 1919, owing to the adverse copper position. The mines are being kept in working order, and an extensive drilling campaign is in hand for the purpose of prospecting adjoining properties at Koperberg and Carolusberg. The metallurgical plant at Rakha Hills had not been finally completed during the year under review, so that the actual output of copper was small, but since the issue of the report a full output of 250 tons of copper per month had been reached. Some of the stocks at the Cape have been sold in New York, and the remainder has been treated at Rakha Hills. During the year, 35,540 tons of ore averaging 3·57% copper was mined at Rakha Hills. The reserve is estimated at 354,688 tons averaging 3·66% copper. The company's accounts for the year show a deficit of £163,627, owing to the virtual suspension of sales. As recorded last month, the company has made provision for further capital by the issue of £120,000 debentures.

Tolima.—This company was formed in 1871 to acquire the Frias silver-lead mine in Colombia. In the early days the operations were highly profitable, but in 1903 and 1909 reconstructions were necessary. During the war great difficulty was experienced in shipping the concentrate and getting it smelted. The report for the year ended June 30 last shows that 7,259 tons of ore was raised and concentrated, yielding 607 tons of concentrate averaging 453¾ oz. silver per ton and 14·87% lead. This material was sold for £63,530. The accounts show an adverse balance of £4,087 for the year. The ore reserve is estimated to contain 1,361 tons of shipping material. During the year there was a brief strike, which led to an increase in miners' wages of 25%. This and the continued rise in the cost of materials makes profitable mining increasingly difficult.

Frontino & Bolivia Gold. — This company was formed in 1864 (being reconstructed in 1886 and 1911) to work a group of gold mines in Colombia, the principal property being the Silencio mine. Pellew-Harvey & Co. are the consulting engineers. The report for the year ended June 30 last shows that 29,760 tons of ore was treated, giving by amalgamation and cyaniding a yield of 25,815 oz. of gold. The profit was £28,161, out of which £4,513 was paid as debenture interest, £2,339 as preference dividend, and £14,000 as ordinary dividend, at the rate of 10%. Labour conditions have prevented the mine from being worked at full capacity. Developments at the lowest level, the 16th, have been good, and the reserve has been slightly increased, standing now at 65,600 tons averaging 16 dwt. per ton. The company has a half share in the Marmajito Mines, Ltd. The plant for unwatering and developing this property has been despatched.

Berenguela Tin Mines.—This company was formed in 1905 to acquire lode-tin properties at Berenguela, Bolivia. Particulars were given in an article in the MAGAZINE for December, 1914. The report for the year ended June 30 last shows that the output of tin concentrate was 386 tons, as compared with 366 tons the year before. The gross trading profit was £41,521, and, after the placing of £14,751 to reserve for contingencies, the net profit was £25,125. Out of this profit, £10,000 has been placed to general reserve, and £10,000 has been distributed as dividend, being at the rate of 25%.

EDITORIAL

A writer in the *Engineering and Mining Journal* of New York estimates the output of gold throughout the world during the year 1920 at £6[illegible],700,000, par value, as compared with £75,000,000 in 1919, and £79,000,000 in 1918. The highest total ever recorded was £98,000,000 in 1915. He reports that the condition of gold-mining in the United States is far from satisfactory, for there is no premium on the metal, and prices of labour and commodities have increased enormously.

A MODEL of the surface plant at the south shaft of the New Modderfontein gold mine has been prepared by the Central Mining & Investment Corporation, under the direction of Mr. H. F. Marriott, and it is now on exhibit at the London office of the company, No. 1, London Wall Buildings. It is to be shown at various places in this country and on the Continent, and it is suitable for the instruction of both the public and the mining student. This plant is an excellent example of latest Rand hoisting and metallurgical practice, and the model is well worth inspection.

IN this issue is published the first half of an article describing the principle of transmission of power by waves of water-compression, and its application in practice, particularly to rock-drills. We have purposely split the article in two, so that readers shall obtain a grasp of the principle before trying to understand the action of the machines. The principle is so novel, and its action in rock-drilling is of such an unaccustomed nature, that engineers will probably take some time to obtain a full grasp of the subject. Next month we intend to say more of the possibilities of the drill. In the meantime it is sufficient to mention that the drill is a practical machine and that several are already at work in mines and quarries.

FIVE years ago Mr. Reginald Le Neve Foster endowed the Royal Society of Arts with a small fund in memory of his father, Peter Le Neve Foster, who was secretary of that society from 1853 to 1879, the proceeds of the fund to be devoted as prizes for the best papers on current subjects of importance. The first offer of the prize was for a paper on the metallurgy of zinc, and the best of those submitted were by Mr. J. C. Moulden and Mr. E. A. Smith. The society now announces a second competition under the terms of the benefaction. This time the subject is the Mineral Resources of China, a subject open to considerable discussion, for opinions vary widely. There are many engineers well qualified to give the records and their views as to the future. It is to be hoped that they will respond to the invitation.

PARTICIPATION in the direction of mining companies is not usually a congenial occupation for a lady, but every now and then opportunity is afforded for the exercise of conspicuous ability in the conduct of mining business. Lady Rhondda is a director of a dozen South Wales colliery companies, and many readers will remember Mrs. Kermode, a director of the Tasmanian Metals Extraction Company. This month the appointment of Mrs. H. J. Tennant to the board of the Champion Reef Gold Mining Company of India is announced. Before her marriage to the son of the late Sir Charles Tennant, she was, as Miss Abraham, the Superintending Inspector of Factories in England, and achieved a distinguished success in that position.

PRECEDENT dating from 1776 interdicts the reference by an Englishman, approvingly or otherwise, to the appointment or candidature of any individual for a public position in the United States. For this reason we refrained from making any comment on Mr. H. C. Hoover's chances of becoming president, and even now it is impossible for us to discuss the outlook for his becoming a member of Mr. Harding's administration. Probably also it is out of order for us to congratulate the United States on the appointment of Mr. H. Foster Bain to the directorship of the Bureau of Mines; but as this is not in the nature of a political position, we feel justified in breaking the time-honoured custom. Mr. Bain is well known throughout the world as an alert geologist and mining engineer, one with an open mind, one desirous of making friends without restriction as to nationality or position. For a few years he edited the *Mining and Scientific Press*, and subsequently he was editor of THE MINING MAGAZINE for a short time. His travels have taken him to many places outside his own country, South Africa, Rhodesia, the Congo, the Malay Peninsula, Burma, China, and Japan. In his new position he will be occupied with much congenial work, and his "soul will not be fettered to an office stool."

Standardization of Mining Materials.

At the meeting of the Institution of Mining and Metallurgy held last month, a subject of considerable interest to the mining profession was introduced by a paper presented by Mr. E. A. Wraight, on the Standardization of Materials employed in Mining and Milling Plant. In order to avoid a misconception as to the scope of the paper, it should be said at once that this discussion relates only to materials employed and not to the design and construction of plant. This latter subject has been to the forefront in certain quarters in the United States recently, where proposals have been made for the evolution of standards for all machinery, beginning with motor cars and including mining machinery and supplies. Mr. Wraight's proposals are confined solely to a discussion as to the best materials for each particular purpose required. This subject has seldom received serious discussion and experimentation, and the reasons are not difficult to recognize, as far as non-ferrous metal mining is concerned. In the first place the persistence of ore is such an uncertain factor in the economics of mining that an engineer or director is seldom warranted in conducting tests or subscribing money to that end. Then again, the conditions of work vary so widely that accurate comparisons are difficult to make. Where the requirements are clearly ascertainable, the funds at disposal unlimited, the labour highly skilled, and competition severe, it is possible and necessary to specify the exact nature of the material to be used for every separate component of the machine. These conditions are not often found in mining. Another difficulty arises from the fact that non-ferrous metal mining is a comparatively small industry. For instance, the Sheffield firms produce special steels suitable for rock-drill purposes, for the wearing faces of ore crushers, and for stamp shoes and dies, but the proportion of their production of steel for these particular purposes is very small compared with the total output of the works, and it is consequently impossible to ask them to make the investigations desired.

Mr. Wraight's paper dealt with drill steel, component parts of stamp-mills, balls and linings for re-grinding mills, facings for Cornish rolls, etc. Even his short statement was sufficient to indicate the bewildering complication of the subject. In the discussion following the presentation of the paper, Mr. Robert Allen gave a brief outline of the work he did in connection with drill steels for the Johannesburg Mines Trials Committee, particulars of which were published in the MAGAZINE for July, 1913; and the subsequent speakers confined their remarks entirely to this branch of the subject. Mr. F. W. Harbord and Professor Carpenter, as leading authorities on the metallurgy of steel, gave their views as to the nature of the steels required for drilling purposes and the behaviour of such steels under forging and sharpening. They considered that theoretically three or more standards would be required, according to the hardness of the rocks, and they doubted whether the expense of such special steels would be warranted unless the smiths in charge of sharpening were fully equal to their work. The general impression obtained from the discussion was that mining operations cannot profitably demand very accurate metallurgical distinctions as regards the steels used, and that better results from the economic standpoint can be obtained with steels having wider ranges of applicability. The discussion at the meeting concluded with a general recommendation that the various mining societies might appoint committees to consider these subjects, and make investigations and suggestions, but it is doubtful whether anything definite can be done in this direction.

Oil on the Waters.

Oil-fuel for steam-raising on board ship presents a good many advantages, as is well known. Absence of smoke during the voyage and of dust during coaling, the rapidity with which the supply of fuel can be taken on board, the great reduction in the number of men required in the furnace rooms, and the ease with which the vessel can be kept in trim all favour the employment of oil-fuel. One of the most serious drawbacks, however, is that the supply of this type of fuel is not unlimited. Reference has already been made in these pages to Admiral Dumas' protests against its indiscriminate use. Since then, one of the leading shipbuilders, Lord Pirrie, head of Harland & Wolff, has also uttered a public warning to the shipowners, telling them that, even at the present rate of consumption, the available supply will come within very narrow compass in twenty years, and that if this method of steam-raising is at all widely expanded the world's resources will be drained long before then. The evil day will, of course, be postponed by the use of the colloidal fuel now being developed by Minerals Separation, seeing that about a quarter of the oil employed in this way will be replaced by fine coal. For this reason the shipping people ought to

pay close attention to the new process. To attempt to induce the shipowners to go slow on oil would be a fatuous proceeding, for, according to the laws of business, profits must always be made when opportunity arises and when good engineering work can be done. In any case it is not a difficult matter to make alterations in the furnaces when it becomes necessary to revert to coal, and moreover it is always possible that a method will eventually be devised whereby fine coal dust can safely be used on board ship without any admixture of oil.

The foregoing considerations with regard to the use of oil-fuel at sea are already well known to engineers, and reference to them is made now only for the purpose of emphasizing the position. A new objection to oil, however, has recently been widely ventilated in the press, and this deserves careful examination with a view to ascertaining the extent of its truth. It is alleged that the oil escaping from the ships has a deleterious effect on marine life, and that as a consequence the fishes and birds stand in danger of extermination. It is alleged that the leakage of oil both from tankers and oil-driven steamers is gradually covering the surface of the sea with a film of oil, of infinitesimal or molecular thinness certainly, but nevertheless sufficient to prevent the aeration of the water and thus check the growth of marine life. The destruction of submarines and the wreck of ships also account for the release of much oil. Another cause of oil getting access to the surface of the sea arises from the practice of filling empty oil tanks with water ballast, and afterwards pumping out the water when the tanks have to be re-charged. This last-named proceeding causes an unpleasant fouling of harbour waters. The first to call public attention to this unfortunate state of affairs was Sir Arthur Quiller-Couch, who uttered a powerful protest against the filthy condition of the roadstead at his beloved Fowey. Anyone who visits the ports patronized by oil-ships can see for himself the unpleasant nature of the surface of the waters, and it can hardly be disputed that in the harbours, and in the approaches by sea toward them, the conditions are distinctly unsatisfactory. It is an open question, however, whether the ocean highways suffer much pollution from the passage of the oil-ships. In fact, they probably suffer less from oil-ships than from coal-ships. With ordinary coal-burning ships, oil escapes into the sea-water circulated through the condensers, while the products arising from the incomplete combustion of the coal, namely, soot, ammonia, acids, and a multitude of organic compounds, eventually reach the water. So the defilement of the track of civilization is not due solely to this new class of offender. There are many other possible causes for the disappearance of fish from our shores than the pouring of oil upon the waters. For instance, vast amounts of imperfect explosives and other chemicals have been dumped in the seas by order of the Government. Then also works and factories on the rivers and sea-board discharge some sort of effluent directly into the sea, and are in fact encouraged to deliver their refuse far out. The authorities are, of course, keen that rivers should not be polluted, but they are not concerned with what happens beyond the limits of the sea-shore. Taking everything into consideration it seems to us that this case against oil is not particularly strong, except from the point of view of the condition of the harbours where oil-ships resort. The Government and the local authorities are competent to deal with this matter. As for the fouling of the open seas, it will be well if it were possible for some scientific body to make an impartial investigation so that the supposed or actual damage can be traced to its ultimate source.

Kirkland Lake.

One of the most important geological reports issued recently is that on the Kirkland Lake gold area, Ontario, made by Messrs. A.G. Burrows and P. E. Hopkins for the Ontario Bureau of Mines. The first section of this report, dealing with the geology and the ore deposits, is published in the Mining Digest elsewhere in this issue, and the remainder, describing the individual mines, will appear in subsequent numbers. Like most of the official technical documents published in Canada, it is up to date and helpful for the present purposes of the prospector and miner. It will be remembered that the same two geologists made a report on the district in 1912, shortly after the first discoveries were made. Thus the pioneers have continuously had every assistance from the Government, and many useful hints for future work have been provided by disinterested parties. Readers of the MAGAZINE will have followed the rise of this centre of gold production, for without intermission news has been published regularly since 1913. In the early days, Mr. Reginald E. Hore, editor of the *Canadian Mining Journal*, gave a comprehensive account, and Mr. J. B. Tyrrell contributed a paper on the subject to the Transactions of the Institution of Mining and Metallurgy. These

authors were followed by Mr. Charles Spearman, who discussed the nature of the ore minerals. For the benefit of those who are not familiar with this district and its history a few notes at this juncture may be given. In reading these notes reference should be made to the maps accompanying the report and reproduced in the Mining Digest.

The Kirkland Lake area forms part of a large mineralized region which extends from Matachewan north-easterly through Larder Lake and into the province of Quebec. There was a gold rush in 1906 to Larder Lake, and during that time many claims were staked at various points between that lake and the railway at Swastika. The Larder Lake boom did not yield any substantial mining success and the district was soon deserted. On the other hand, a property at Swastika, and subsequently an adjoining property known as the Lucky Cross, proved profitable. These successes and the concurrent progress at Porcupine served to draw attention once more to this area. The first gold discovery at Kirkland Lake was made in 1911 by Mr. W. H. Wright, who staked out claims which are now parts of the Wright-Hargreaves mine. By the end of that year nearly the whole of the ground was re-staked. Early in the next year gold was found on the Tough-Oakes claims to the north-east of the lake. These early discoveries did not reveal any particularly attractive ore, and it was not until 1913 that rich ore found on No. 2 vein of the Tough-Oakes workings brought the district into prominent notice. During that year much surface trenching was done, and a number of promising veins were found on the Burnside, Sylvanite, Wright-Hargreaves, Lake Shore, Teck-Hughes, Orr, Kirkland Lake, and Hunton claims. At first the ore raised at the Tough-Oakes was hand-sorted, and the picked ore sold to smelters. As an indication of the nature of the ore it may be mentioned that during 1914 the assay-value of the ore mined was $41 per ton; the amount of high-grade ore shipped was 212 tons, averaging $350 per ton, while a 5-stamp mill treated 3,493 tons, averaging $22 per ton, extracting 55% of the gold content. In 1915 capital was provided for the erection of a treatment plant on the continuous cyanide system, having a capacity of 100 to 125 tons per day. During the year 1916 this plant extracted gold worth $700,000. In this year also a mill was built on the Teck-Hughes mine, working on much the same system as that at the Tough-Oakes, but at this property the average assay-value of the ore is much lower. During this time development was continued at the Lake Shore, and in 1916 work was commenced on the Wright-Hargreaves and the Kirkland Lake properties. Toward the close of 1917 mills were built for the Lake Shore and Kirkland Lake. In 1918 the Tough-Oakes mine was closed owing to the developed ore being exhausted and no development having been done, but mining operations were resumed next year in conjunction with the Burnside. In 1919 three mills were in operation at the Kirkland Lake, Lake Shore, and Teck-Hughes, while mills were being built on the Burnside and Wright-Hargreaves. During these latter years there were many interruptions owing to scarcity of labour, high wages, and increased cost of supplies, and a strike of four months' duration also supervened. The district has also suffered owing to disputes relating to the transfer of ownership of some of the properties to an English company, the Kirkland Lake Proprietary. These difficulties were fortunately overcome a little over a year ago by the amalgamation of that company with the English Tough-Oakes, Sylvanite, and Burnside companies, and a new campaign of development has been commenced.

It is expected that the yield of gold during 1920 will be worth about a million dollars. This may seem small compared with the output at Porcupine, but nevertheless the importance of the Kirkland Lake district is considerable. The lodes are plentiful, and in places the ore-shoots are rich. Further prospecting promises to give excellent results through a large area of country in all directions. As will be seen by a perusal of Messrs. Burrows and Hopkins's report, the gold, accompanied by tellurides, is found in an extensive series of fractures. This fracturing crosses all the rocks, which include felspar-porphyry, syenite, lamprophyre, and conglomerate. The gold is most plentiful in lodes contained in the porphyry, and it is probably genetically connected with that rock. It is clear from the geological description that the Kirkland Lake district will well repay further and continuous investigation

Libel and Criticism.

Last month brief notice was made in these columns of a pronouncement made by the Lord Chief Justice, in the course of a libel suit, to the effect that he felt impatient when he was told that the offending articles were written as a public duty, adding: "You did it in the ordinary course of business." Such an expression of opinion coming from the head of the English Bench is, to say the least, disconcerting, and is likely to make an editor feel and

look small when confronted with the majesty of the law. Seeing that the policy of the MAGAZINE has always been to express opinions freely, it is clear that we come within the scope of the Lord Chief's dictum, and for that reason several readers have asked us for a definite statement as to our general views with regard to criticism and libel. We would say, to begin with, that all personal criticism is repugnant to us and to 99% of the technical editors of the world. In the first place, it makes enemies and brings no new friends; and secondly, a libel action distracts the editor's attention from his proper occupations and involves him and the proprietors in unlimited legal expenses. Thus from both points of view it is not "business." Here it should be observed that we are concerned only with libel in technical publications, and that the offending journal appearing in the Lord Chief's court was devoted to a branch of engineering. It is necessary to call attention to this fact, for it is well known that certain types of popular papers welcome libel suits as they afford means for securing publicity and advertisement. Moreover a personal libel is often associated with blackmail, and as such constitutes one of the most unsavoury phases of evil-doing. It is possible, of course, that the Lord Chief saw no distinction between these two classes of libel, and that he would not even recognize the possibility of such a distinction. The fact is that most lawyers of good standing do not particularly relish the duty of defence in a libel action, however great may be the integrity of the author of the alleged libel. Their attitude on the subject, both physically and mentally, is usually reminiscent of Mr. Pickwick's famous interview with Serjeant Snubbin. "Mr. Serjeant Snubbin unfolded his glasses, raised them to his eyes, and, after looking at Mr. Pickwick for a few seconds with great curiosity, smiled slightly as he spoke. . . . The smile on his countenance became more defined, and throwing himself back in his easy chair, coughed dubiously. . . The serjeant tried to look gravely at the fire, but the smile came back again."

From the foregoing remarks it is obvious that irritant criticism is not a "business" proposition for an editor of a technical journal. On the other hand, the editor has to think of the honour and reputation of the profession which his paper seeks to represent. Mining is unfortunately not free from public reproach, and in some quarters it is even classed with gambling and swindling. Thus it is incumbent on the editor of a mining paper, in the way of "business," to say something in protest when mining propositions resting on insecure foundations are placed before the public, for, when ventures of this character collapse, it is usually mining and the mining engineer that are blamed, and not the organizers of the schemes. Thus, in spite of his repugnance, the editor has to imagine that it is his duty to his profession and to the public to point out the absence of any real basis for such ventures. But it is impossible to embark on such an attempt at exposure unless there is ample confirmatory evidence of the unsoundness of the ventures in question. It would surprise our readers to know how many grievances are brought to our notice which are not suitable for public comment. Some of them are real enough, but the faults are often due more to lack of personal judgment than to evil intent, while others are not substantiated by evidence acceptable in a court. Comment could never be made by an editor on any grievance that rests on a difference of opinion between two members of the profession, or on any allegation against a member of the profession made by an outsider. Such matters are not of public interest, and adjudication on them rests entirely with the Council of the Institution.

There is another point of view in connection with the presumed "public duty" that remains for consideration. After an editor has persuaded himself of this public duty, the question usually arises within his mind as to whether the public will ever thank him for drawing attention to the lack of basis for a particular venture. On the failure of the properties, or on the exposure of their barrenness, the shareholders find their shares unsaleable, or saleable only at an absurdly low price, and their attitude of mind is naturally bitter. The editor who issued the warning is an unpopular person, for he has knocked down the house of cards, and has prevented the shareholders from realizing their shares, and he is certainly unable to offer them any solatium. On the other hand, the promoter or the board may be often in a position to help the shareholders to retrieve a part at least of their losses. In any case the average subscriber to mining shares does not read the technical mining papers, so it seems little use from the "public-duty" point of view for such papers to utter these warnings. Thus we are faced with the conclusion, which seems like a reductio ad absurdum, that, whether considered from the point of view of "public duty" or of "business," libel and criticism do not pay. Nevertheless, a spice of criticism partakes of the nature of an imponderable asset, which, though indefinable, is none the less real.

REVIEW OF MINING

Introduction.—The world is now passing through a serious trade crisis. Metals are quoted at prices a long way below the average cost of production, and stoppages, partial or total, are announced in many quarters. The position of the Cornish tin industry is very serious, for hardly any actual mining is being done. The gold industry exists largely on the premium at present obtainable. In business circles there is gratification at the forthcoming withdrawal of the Excess Profits Duty, though the real reason for the change of front on the part of the Government is gloomy enough.

Transvaal.—The output of gold in the Transvaal during the year 1920 amounted to 8,153,625 oz., as compared with 8,330,091 oz. in 1919 and 8,418,292 oz. in 1918. In 1912, 1915, 1916, and 1917, the totals exceeded nine million ounces, and the highest figure was 9,296,618 oz. in 1917. The par value of the 1920 output was £34,652,700, but owing to the premium the value of the gold was estimated at £44,640,420. It will thus be seen that approximately £10,000,000 was received as premium. When it is added that the dividends declared during the year amounted to £8,314,300, it becomes clear how much the Transvaal gold-mining industry depends on the premium for its profits.

The new Currency Act of the Union came into force on December 17, and so far the mail accounts show that the disappearance of the gold coins has been accepted without complaint or comment. The attitude of the natives toward paper money was carefully considered before the change was made, and the supply of silver coin was increased so that as far as possible native wages should be paid in hard cash. In some quarters the substitution of paper for gold gave rise to uncertainty among the natives, but the position was so fully explained by the Government and by the various employers that there was no serious trouble. The authorities have handled the matter with much more common sense than was shown by those responsible for paper money in West Africa.

A strike of white miners has put Consolidated Langlaagte out of action for the time. The cause is imperfectly understood in this country. There are rumours that the men's Union contemplate a general strike, but this may be only a ruse in connection with the elections. At the time of going to press little definite news has come to hand.

The directors of Modderfontein East have completed the negotiations, to which reference was made in the December issue, for the purchase of the Simmer Deep and Jupiter milling plant. The figure agreed to is £110,000. The capacity of the plant as it stands is 80,000 tons per month, but only 50,000 tons is to be treated at Modderfontein East.

No. 4 vertical shaft in the new section of Brakpan has reached the reef at a depth of 4,218 ft. The average of the assays gave 7·6 dwt. over 39·2 in. The foot-wall leader, included in the foregoing measurement, averaged 15·3 dwt. over 18·4 in.

The ore-reserve position at Geduld continues to show advances. The figures at December 31 were estimated at 3,220,000 tons averaging 8 dwt. per ton, as compared with 2,580,000 tons averaging 7·4 dwt. the year before, in both cases the stoping width being assumed at 61 inches.

Brief mention is made in the directors' report of the Messina company, and in the chairman's speech at the meeting of shareholders, of the new project for establishing a copper smelter and refinery to treat the ores produced at the company's mines. The building of this plant is in the hands of a new company, the Transvaal Smelting & Refining Co., Ltd. Its business will not be confined to the smelting of the Messina ores, for it is intended also to purchase copper ores from mines now being opened up in the same district. The Messina mines were closed some months ago owing to continued rises in costs and the fall in copper, and the labour force was transferred to the erection of the company's new concentrating plant and of the smelting company's furnaces. Mining will not be recommenced until the new plants are ready.

Rhodesia.—The output of gold during the year 1920 was 552,498 oz. and the estimated amount obtained by its sale was £3,056,549. This figure is really slightly higher than it should be, for in May there was included among the receipts an unspecified amount representing premium on the outputs during October, November, and December, 1919. At present the biggest producers are the Shamva, Lonely, Falcon, and Globe & Phœnix, of which the first two exhibit the healthiest symptoms as regards the future.

The British South Africa Company has issued figures for the output of metals and minerals in Southern Rhodesia during 1920.

These are given in the following table, together with the figures for 1919.

		1919	1920
Gold	Oz.	593,222	552,497
Silver	"	172,000	158,982
Copper	Tons	3,012	3,109
Chrome Iron Ores	"	35,282	60,269
Asbestos	"	9,799	18,823
Coal	"	510,040	578,492
Tungsten Ores	"	20	17
Arsenic	"	242	437
Antimony	"	--	11
Ironstone	"	2,500	—
Mica	"	6	97
Tin	"	4	4
Diamonds	Carats	385	243

The market value of the gold produced in 1920 is given at £3,056,549, as compared with £2,499,498 in 1919. Though the output was 39,000 oz. less, the amount received by the mines was £557,000 greater, owing to the premium ruling for gold.

The Lonely Reef continues to give good results in depth. On the 24th level the ore is found to assay 39·9 dwt. over 44 in., and development of this level has been started.

The Cave Commission has at last presented its report as to the amount due to the British South Africa Company for administration expenditure on behalf of the Crown. The company claimed the amount of £7,866,117 up to July, 1919. Against this, the award of the Commissioners is £4,435,225 up to the end of March, 1918, but a good many items based on valuations may have to be reargued.

The desire of the residents in Rhodesia for responsible self-government has been before Lord Milner, Secretary of State for the Colonies, for some time past owing to the result of the election to the Legislative Council in April last of twelve out of thirteen members pledged to demand the immediate grant of this form of government. Lord Milner recommends that this question should be postponed until the election in 1923. Owing to the charter of the British South Africa Company expiring in 1924, it is clear that the future government of the country will then come up for consideration, and the elections for the council in 1923 would naturally be the proper time for registering public opinion. Lord Milner, in the meantime, proposes that for the next three years the British Government should advance certain sums required for public works, owing to Rhodesia not being in a position to raise loans in the open market. The members of the council do not accept these proposals for delay and have addressed Lord Milner once more on the subject.

Congo.—An outline of the yearly report of Tanganyika Concessions, together with a new official map of Haut Katanga, are given elsewhere in this issue, as is also Mr. Robert Williams' speech to shareholders. The most interesting item of news relates to the formation of the Nile-Congo Divide Syndicate, which has secured an 80% interest in certain mineral rights in the Sudan along the Nile-Congo watershed. The syndicate has a capital of £35,000, of which Tanganyika Concessions has subscribed £10,000, with an option to take up 5,000 more shares within five years. The leading spirit in this enterprise is Major Christy, who, together with Mr. Robert Williams, has had evidence for some time that the region would repay prospecting for minerals. It will be remembered that the north-eastern part of Congo State, which is also on this watershed, contains a number of rich gold deposits.

West Africa.—The Prestea Block A company reports that the main ore-shoot is showing serious signs of exhaustion. The only recent accession to reserves was in a length of 90 ft. on the 12th level between the North and the Appantoo shafts, averaging 44s. over 110 in. A winze is being sunk to ascertain how far the ore continues downward. On the 11th level a newly discovered shoot is being developed, where the ore averages 45s. 6d. over 107 in. for a distance of 310 ft. On the 12th level the ore averages 37s. over 126 in. for 635 ft. The immediate future of the mine depends on how this shoot develops in length and breadth.

Nigeria.—The persistent slump in tin is giving most of the producing companies an anxious time. Not only is the price low, but sales are not promptly effected, so that the financial position of most of the mines is by no means secure. As regards the issue of £25,000 debentures by the Jantar company, announced last month, the response has been so poor that the issue has been withdrawn, and orders have been given to cease work at the properties at the end of April unless the tin market substantially revives.

Australia.—The Broken Hill industry is fated to receive one set-back after another. The latest disaster is the burning of part of the Associated Smelters' plant at Port Pirie, the sintering section being the chief sufferer. It is estimated that damage to the extent of £100,000 has been done. The official cable states that the question of replacement and the erection of temporary plant for use in the meantime is receiving the consideration of the board.

The position at the Broken Hill mines remains obscure. It is obvious that the discussion on reduction of work owing to low prices of metals is now complicated by the fire at Port Pirie. The Zinc Corporation announces that mining is to be stopped at the South Blocks,

and that the only material to be treated is the old zinc tailing. It will be possible to realize on the zinc concentrate produced, for the British Government is still bound by the contract to purchase such concentrate for 10 years from 1916.

The railway strike which caused the stoppage of work at the Kalgoorlie mines, mentioned last month, has terminated and work has been resumed.

The shipping strike, to which reference was made last month, has had the effect of preventing the delivery of iron ore from South Australia to the Broken Hill Proprietary's blast-furnaces at Newcastle, New South Wales. The consequence is that the blast-furnaces will be closed down shortly, and afterwards the steel plant and rolling mills.

A serious fire occurred at the Sons of Gwalia on January 19, a large part of the surface plant being destroyed. The fire broke out in the gas-engine house, and it eventually damaged the milling plant and the air-compressor. The headgear, hoisting engine, slime plant, and extractor-houses were saved.

Boring for oil is to be undertaken in Gippsland, Victoria, by a company that has recently been formed called the Austral Oil Wells, No Liability. The drilling is to be done in the Morwell and Omeo districts. The occurrence of oil in this region has been observed for many years, but no exploratory work appears to have been done. The Wonthaggi and Morwell coal deposits are in this part of Victoria.

The Anglo-Persian Oil Company has made proposals to the Government of West Australia with the object of prospecting for oil in that state. The company is prepared to spend £50,000 in geological-survey work and boring. The Government appears to be disinclined to grant such large concessions as the company desires.

New Zealand.—The Waihi Gold Mining Co. announces that a proposal is to be made for the reduction of the nominal value of its shares from £1 to 10s., and the return of £250,000 to shareholders. The company has large assets in first-class securities representing about half-a-million pounds, virtually representing the nominal capital. It also has £212,500 in New Zealand bonds redeemable in ten years' time, received as purchase price for the Hora-Hora hydro-electric installation. The company has been working much poorer ore during the last few years than that which made so great a name for the mine. For some time efforts have been made to secure a new property, but so far without avail.

India.—The Burma Corporation announces that its output of refined lead during 1920 was approximately 23,816 tons and of silver 2,874,000 oz., as compared with 18,540 tons and 2,168,000 oz. respectively in 1919. Of the shipments of lead during 1920, 9,200 tons came to London and 16,312 tons went to India and the Far East. At the present time the demand for lead in the Far East is increasing so much that nearly the whole of the output is now absorbed there and hardly any is coming to London.

Cornwall.—The collapse of the tin market is having a disastrous effect on the Cornish tin mines. Our Camborne correspondent gives some account of the present sad plight of Cornwall. Every mine has closed down as far as production is concerned, and the difficulty will be to provide funds for pumping and keeping the mines in good condition. Attempts to keep Grenville going have failed and the company has gone into liquidation.

The two petitions for the compulsory winding-up of the Calloose Tin Mines & Alluvials, Ltd., have been dismissed by the Court. Mr. H. Newhouse and other shareholders, who had previously successfully petitioned for a removal of their names from the register, have had their claims against the company paid in full, so that their action was annulled. The other petition, brought by the Naraguta (Nigeria) Tin Mines, Ltd., was not pressed. The company is now free to try other properties, and the famous "Calloose" incident is at an end.

Devon.—A few months ago it was announced that Mr. H. Mallaby-Deeley, chairman of the company, had acquired the property of the China Clay Corporation at Redlake and Ivybridge, which was sold by the order of the Court. It is now announced that the amount paid was £47,000, and that a new company is to be formed with a capital of £75,000. Of this capital Mr. Mallaby-Deeley will take £47,000 in shares as purchase price, while 28,000 shares will be offered for subscription among shareholders in the old company. The old company had an issued share capital of £270,000, and there were £34,264 debentures, and it had spent nearly £200,000 on equipment. The new board is to be composed of men conversant with the china-clay business, so the actual value of the deposits should soon be ascertained.

Oil in Great Britain.—The Government Petroleum Department has issued a report on oil-drilling operations during 1920. The Hardstoft well continues to yield oil by natural overflow at the rate of 1 ton per day, and the

output for 1920 was 375 tons, of which 325 tons has been sold to the Anglo-American Oil Co. at £22. 10s. per ton. At Ironville No. 1, also in Derbyshire, there was a good showing of thick oil at a depth of 2,031 ft., at the junction of the Limestone Shales and the Carboniferous Limestone, and there were also shows in the Limestone at 2,500 ft. and 3,630 ft. At the latter point the well was shot with 180 lb. of dynamite, but with what result is not yet known on account of water in the well. At the Heath well a good show of light filtered oil was encountered at 3,940 ft. At the D'Arcy well, near Edinburgh, gas was tapped at 724 ft., with a flow of approximately 300,000 cu. ft. per twenty-four hours. At West Calder, near by, the bore gave indications of oil at several points, but the presence of volcanic rocks caused much trouble.

Canada.—The average man would never expect hydro-electric power to fail in Canada owing to shortness of water. Such, however, has been the case recently in Northern Ontario, with the result that at Porcupine and Cobalt the output of ore has been limited by the rationing of current. Our Toronto correspondent refers to this matter in his news letter published elsewhere in this issue.

United States.—The United States Geological Survey reports the output of gold in the individual states during 1920 as follows, the figures for 1919 being appended also for comparison.

	1919 $	1920 $
California	16,695,900	14,305,300
Alaska	9,036,000	7,856,000
Colorado	[illegible]	7,613,000
Arizona	4,506,400	4,493,000
South Dakota	4,862,500	4,201,400
Nevada	4,451,500	3,554,900
Utah	2,159,400	2,076,400
Montana	2,229,600	1,839,200
Oregon	980,800	965,100
Idaho	713,200	465,300
New Mexico	[illegible]	463,400
Washington	252,800	148,800
Totals	60,300,000	50,000,000

It will be seen that the decrease in production continues, and that the fall is general throughout all the States.

The Bunker Hill & Sullivan Company, of Idaho, recently built a lead smelter, and now produces its own lead instead of selling concentrates. The directors have since decided to start an electrolytic zinc plant. The Star mine contains complex ore, and this is to be treated for the production of lead and zinc concentrates, the latter to be used for zinc production. The initial capacity of the zinc plant is to be 25 tons per day, and the cost is estimated at a million dollars. It is hoped that the zinc market will have revived by the time the plant is built.

The condition of the zinc industry in the United States is reflected in the fact that work at the electrolytic plant at Anaconda has been suspended owing to the low prices ruling.

It is announced that vanadium is not now produced from Colorado ores, which consist of carnotite, the mineral yielding also uranium and radium. The whole of the vanadium used in America is now made from Peruvian ores, and it is stated that such vanadium is purer and cheaper to prepare than that made from Colorado ores.

Mexico. — Last month a brief cable was received in this country announcing the bursting of a dam at Pachuca and the consequent flooding of several mines. No confirmatory news is to hand yet. The Santa Gertrudis company announces a shortage of hydro-electric power, which will result in some contraction in the scale of operations at its various mines. Whether the shortage is caused by the accident referred to or by drought is not stated.

Bolivia.—It has already been recorded that the main reserves at the Porco tin mines have been exhausted and that the mill has been kept going chiefly on custom work. Owing to the low price of tin, it has now been decided to suspend mining and milling operations. It is felt, however, that the property should not be abandoned without some more prospecting being done in depth. A proposal is therefore being made that the shares shall be written down from £1 to 5s., and that shareholders shall be invited to subscribe a further 5s. per share. The alternative will be a foreclosure by the debenture holders, Messrs. Avelino Aramayo & Company.

Some months ago Mr. Justice Russell decided that certain dividends distributed by the Aramayo-Francke Mines, Ltd., to its German shareholders during the war should have been paid instead to the Public Custodian in this country. The company had large assets in Germany and the directors felt justified in paying dividends out of those assets to the German shareholders. An appeal from Mr. Justice Russell's judgment was before the Court of Appeal last month, and the three judges unanimously upheld the decision of the court below. It was maintained that the Custodian was the shareholder under English law. It seems hard lines that the company should not be allowed to consider the dividend as paid out of funds which had probably already been confiscated by the German Government, but the legal interpretation of the Act is presumably the correct one.

THE TRANSMISSION OF POWER BY WAVES.

By P. J. RISDON.

Particulars are given in this article of the new method of transmitting power by wave motion, invented by G. Constantinesco and developed by W. H. Dorman & Co., Ltd. Particular reference is made to the application of the system to the driving of rock-drills.

ON several occasions reference has been made in the columns of THE MINING MAGAZINE to a new rock-drill operated by means of power transmitted in waves through water. This article gives an outline of the theory of the new process, while another article to follow will give details of the construction of the various apparatus.

This important new system of transmitting power is the invention of a Roumanian, Mr. G. Constantinesco, while credit for developing it, so that it is now a practical and commercial proposition, is due to Messrs. W. H. Dorman & Co., Ltd., of Stafford. The first application of the system was in the synchronization of machine-gun fire with the revolutions of aeroplane propellers. The device enabled 2,000 shots a minute to be fired between the blades when revolving at high speed without the possibility of a single bullet striking a blade. This was known as the C.C. Interrupter Gear. The use of the principle involved has now been extended and applied so that a wave generator can transmit waves of 10 h.p. through water in a pipe 1 in. diameter.

THEORY OF WAVE TRANSMISSION.—At first sight the system might be mistaken for a form of hydraulic transmission, but in point of fact it is based upon an exactly opposite principle. In hydraulic transmission, use is made of the fact that water is only compressible to such a small extent that it serves the same purpose as a long flexible piston rod, the water being propelled bodily through a pipe and expelled from the cylinder upon completion of the stroke. In wave power transmission, the water does not move bodily forward, nor is it expelled, but remains in the system. In this case, the method depends upon the fact that water *is* slightly compressible or elastic. Assume that we have 150 metres of wrought-iron steampipe of 2·5 cm. diameter and 0·5 cm. thickness of metal, closed at one end and filled with water; and suppose a fluid-tight piston is forced into the pipe under a steady pressure of 35 kg. per sq. cm. If the liquid were incompressible the increase in volume of the containing pipe under the pressure would allow the piston to enter about 1·5 cm. If the pipe were absolutely inexpansible the pressure would compress the water to an extent that would allow the piston to enter about 26 cm. It is seen, therefore, that the compression of the water in a wrought iron steampipe of the size considered is the chief factor in the changes of volume that take place under pressure, and that the expansion of the containing pipe is almost negligible. On removing the pressure from the piston, the water will again expand to its original volume.

With other liquids similar results will be obtained. Consider what takes place in a speaking tube when the contained air is set in motion by a diaphragm, in a plane normal to the axis of the tube, that vibrates about a mean position. The first movement of the diaphragm in the direction of the tube displaces some air in the tube; this displacement is resisted by the still air farther along the tube, so that a zone of compressed air is produced in the immediate neighbourhood of the diaphragm. At the same time the moving diaphragm is giving velocity to the particles of air in its immediate neighbourhood, and these particles communicate their velocity to those beyond them, and thus any disturbance once produced by the diaphragm must travel forward along the tube. On the return movement of the diaphragm, the compressed air in its immediate neighbourhood, being elastic, expands, and we have then a zone of low-pressure air in contact with the diaphragm. The continuing vibrations of the diaphragm produce alternate zones of high and low pressure, and the disturbances so produced travel forward along the tube until the whole of the air particles in the tube are in a state of vibration; it has been found that the zones of high and low pressure travel along the tube with a definite velocity of about 1,100 ft. per second, this velocity varying slightly with the diameter of the tube. In a similar manner sound energy travels through other elastic media. The velocity through water has been found to be about 4,800 ft. per second.

As hitherto employed for the transmission of power in hydraulic systems, liquid and solid connections have been considered as movable en bloc, and for practical purposes incompressible and inextensible. Both liquid and solid columns, however, are elastic, and this property

can be made use of to transmit energy by vibrations of the particles of matter of which they are built up. We will now consider the case of liquid columns.

Assume that a pipe, instead of being closed rigidly at one end, is closed by a light floating piston held always in contact with the liquid column, but free to move with the liquid; assume further that the working piston, instead of being slowly pushed into the pipe, is connected to a rapidly rotating crank, so that it moves with a simple harmonic motion, and that, in addition to the piston impulses, a steady pressure acts on the liquid column at both ends. The only resistance to the movement of the piston is then the inertia of the liquid column, and if the column is short the liquid will move as a solid mass. If, however, the column is of considerable length the motion of the layers of liquid nearer the working piston is resisted by the inertia of the more remote layers, and on the in-stroke of the piston the liquid in its neighbourhood will be compressed and its volume diminished; it follows that the motion of the layers of liquid remote from the piston will be but very slightly less than that of layers nearer to it.

At any given speed of rotation of the crank there will be a point in the liquid column at which, on the completion of the in-stroke of the piston, no movement of the liquid has occurred. The liquid between this point and the piston will at this moment be in a state of compression, varying from a maximum at the piston to zero. At the moment of maximum velocity of the piston, the velocity of the layer of liquid in contact with it will necessarily be greater than the velocity of the more remote layers, and the kinetic energy of the layers nearer the piston will, therefore, be transmitted in the forward direction along the column. The energy expended by the piston in its forward stroke at the end of this stroke is present in the liquid column, partly in the form of potential energy due to the decreased volume of the liquid under compression and partly as kinetic energy.

On the return stroke of the piston, the compression of the layer of liquid in contact with it decreases, and expansion of the liquid takes place between the piston and the point in the column at which the pressure is a maximum. As the point of maximum pressure moves away from the piston at the commencement of the return stroke, the velocity of the layer of liquid in contact with the piston is reversed, while the pressure of this layer diminishes until the piston is at the end of its out-stroke. At the end of this out-stroke the layer of liquid in contact with the piston is for the instant at rest. As the crank continues rotating, there are thus impressed on the liquid column a series of impulses sending a series of changes of pressure and volume along the column, the particles of liquid each vibrating about a mean position.

In order that a receiver may be able to respond to the vibrations falling on it, certain conditions are essential. The part of the receiver which is to be put in action must be capable of vibrating at the periodicity of the vibrations which fall on it. Thus when it is desired to transmit power economically by means of vibrations, it is necessary that the part moved should be designed so that it can respond to the particular periodicity of vibrations at which the power is transmitted. It is further necessary, if the part moved has to perform useful work, that the work should be performed in such a manner that the ability of the receiver to vibrate in unison with the impressed vibrations is not interfered with.

Let us now consider further the case of a rapidly-rotating crank causing a piston to reciprocate at the end of a long pipe containing liquid. We have seen that a series of zones of high pressure and compression of the liquid alternating with zones of low pressure and expansion of the liquid are produced, and that these zones travel forward along the pipe.

In Fig. 1, suppose the crank A to be rotating uniformly, causing the piston B to reciprocate in the pipe C which is full of liquid. At each in-stroke of the piston a zone of high-pressure is formed, and these zones of high pressure, shown by shading, travel along the pipe away from the piston; between every pair of high-pressure zones is a zone of low pressure, shown light in the figure. The pressure at any point in the pipe, therefore, will go through a series of values from a maximum to a minimum, and these values will repeat periodically. Let the line OX represent the value of the mean pressure; then, with the piston in the position illustrated, the instantaneous pressures at different points along the pipe may be represented by the ordinates of the sine curve EFG . . K. As the rotation of the crank is uniform, it will be evident that the distances between successive points of maximum pressure will be equal. This uniform distance along the pipe at which the values of the pressure are repeated is the wave length of the vibrating movement of the liquid. If v is the velocity with which these waves travel along the pipe, and n is the number of revolutions in unit time of the crank A, it will readily be seen that the wave length y must be $\frac{v}{n}$.

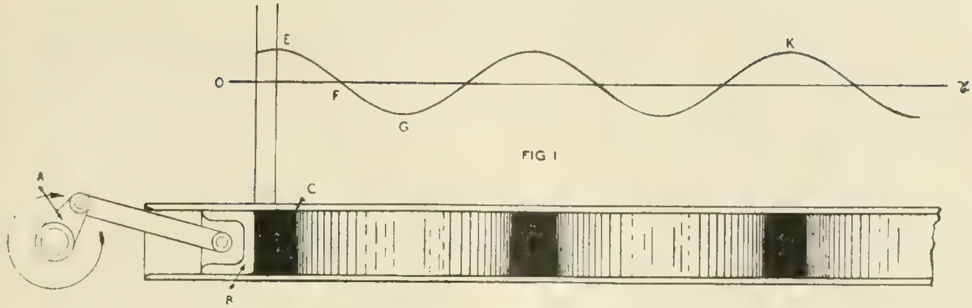

FIG 1

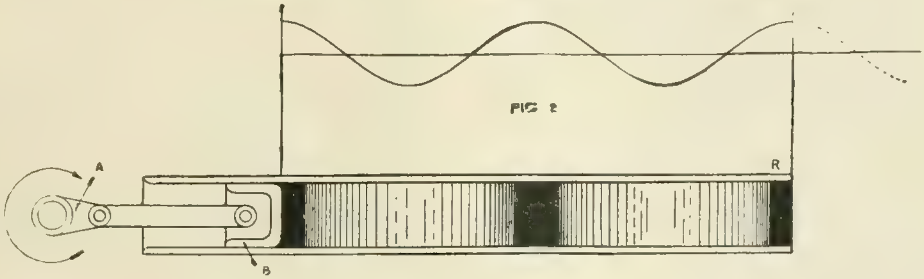

FIG 2

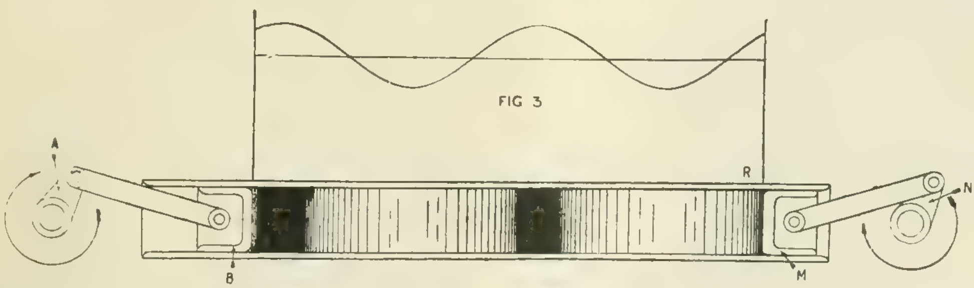

FIG 3

Assume now that the pipe is closed at the point R at a distance from the piston B equal to an exact multiple of the wave length, and suppose that the stroke of the piston is small compared with the wave length, as shown in Fig. 2. The wave of compression will be stopped at R and reflected, and the reflected wave will travel back along the pipe.

If the crank continues its rotation at uniform speed, with the length of pipe and speed of rotation we have taken, that is, with the distance from the piston B to the stop R, an exact multiple of the wave length, a zone of maximum pressure will be just starting from the piston at the instant the reflected zone of maximum pressure reaches it ; so that we shall have a wave of double the original amplitude travelling forward along the pipe. The next revolution of the crank will again add to the amplitude of the wave sent forward, and so on with successive revolutions. The result of this continual pouring in of energy is that the maximum pressure increases without limit until ultimately the pipe bursts.

It should be noted that, in a wave of greater amplitude, the maximum pressures are increased and the maximum velocities and distance of travel of the oscillating particles are also increased.

Suppose now that instead of closing the pipe rigidly at R, we have at R a piston M connected to a crank N similar to A, as shown in Fig. 3. Suppose that the crank N is rotating at the same angular velocity and in the same phase as the crank A. If the liquid column were continued beyond the piston M, it is evident that the movement of the piston would produce in this column a series of waves which would be exactly similar to and a continuation of the waves between B and M. The piston M, therefore, if moving synchronously with B, will be able to take up the whole energy of the waves produced by B and travelling along the pipe. It will be seen, further, that the piston will be able to take up and utilize the whole of the energy of the waves travelling to it if placed at any point of the pipe, provided its time period of reciprocation is the same as that

of the piston A, and provided that the phase of its movement is such as would produce a continuation beyond it of the impinging waves; that is to say, provided the piston movement is in phase with the movement of the layer of liquid in contact with it.

In the transmission of power by wave motion in this example, the maximum pressure in the pipe will at no point exceed the maximum pressure in the neighbourhood of the working piston, however long the transmission line may be; and will be the same whether the line is a single wave length or any number of wave lengths. Also the two pistons may be moving in the same or in opposite directions, and their motions may differ in phase by any angle according to the relation between the distance from one to the other and the wave length.

In the example above discussed, the whole of the energy put into the liquid column by the piston B can be taken up by the piston M. If more energy is put in by B than is taken up by the piston M, assuming no frictional losses, it is obvious that reflected waves must be formed as the direct waves fall on the piston M. The result of this will be that the surplus energy will remain in the liquid and the continuation of the rotation will continually pour in energy, increasing the maximum pressure indefinitely, until ultimately, as in the case of the closed pipe, the pipe will burst.

Suppose that, in the case of a closed pipe having a length of several wave lengths, a vessel D, completely filled with liquid, of considerable volume in proportion to the stroke volume of the piston B and with rigid walls, is placed in communication with the pipe in the neighbourhood of the piston, as shown in Fig. 4. At each in-stroke of the piston a flow will take place through the entrance to the vessel D, and the liquid in this vessel will be compressed; at each out-stroke of the piston the liquid in the vessel will again expand, and, according to the volume of the vessel, more or less liquid will flow into it and out of it at each revolution of the crank. The water in the vessel D will thus act as a spring, taking up the energy of the direct and reflected waves when the pressure is high, and giving back this energy when the pressure falls; the mean pressure in the vessel D and in the pipe will be the same, so that when the successive reflected waves in the pipe have been produced and have reached a certain amplitude equivalent to this mean pressure, the piston will merely exert energy in compressing the liquid in the vessel D on its in-stroke, and the liquid acting as a spring will restore this energy to the piston on its out-stroke. The result of this is that, when the reflected waves have been produced, there will be a series of stationary waves in the pipe, and no further increase of energy in the liquid will take place and the pressures in the pipe will never exceed the fixed limit.

By using a vessel such as D, therefore, the pipe can be completely or partially closed. It is therefore possible to place at the far end or other point of the pipe apparatus for utilizing only part of the energy of the wave, and the rotating crank A will only require to perform work to the extent of the energy actually utilized.

Consider now a case (Fig. 5) in which waves are transmitted by a reciprocating piston A along a line E-E-E provided with branches. Assume that the pipe E is closed at P at a distance of one complete wave length from the wave generator A, and that there are branches B,E,D, at the half, three-quarter, and full wave length distances respectively. We know from the cases discussed above that if the cock P is closed and the cock D open, leading to a motor L rotating at the synchronous speed, the motor L will be able to take up the whole of the energy put into the liquid by the generator.

We also know that if all the cocks are closed, stationary waves will be produced in the pipe E having maximum variations of pressure at the end P and at the half wave length B. At these points the flow will always be zero, while the pressure will alternate between maximum and minimum values determined by the closed vessel F filled with liquid. At the quarter and three quarter wave length G and C respectively the flow will alternate between maximum and minimum values, but the variation of pressure will remain zero.

In this case the points of maximum pressure and maximum movement do not travel along the pipe but are fixed in position, and theoretically no energy flows from the generator. At the points of maximum movement no variation of pressure will occur; and at the points of maximum pressure variation there will be no movement of the liquid. It is evident, therefore, that if the cock B leading directly to a motor M be opened, the motor M, running at the synchronous speed, will be able to take up all the energy given to the line. The stationary half-wave between A and B will therefore disappear, its place being taken by the forward travelling wave, while between B and P the stationary wave will persist. If the cock C leading to the motor N at the three-quarter wave length be opened, all other cocks being closed, since at the point C the variation of

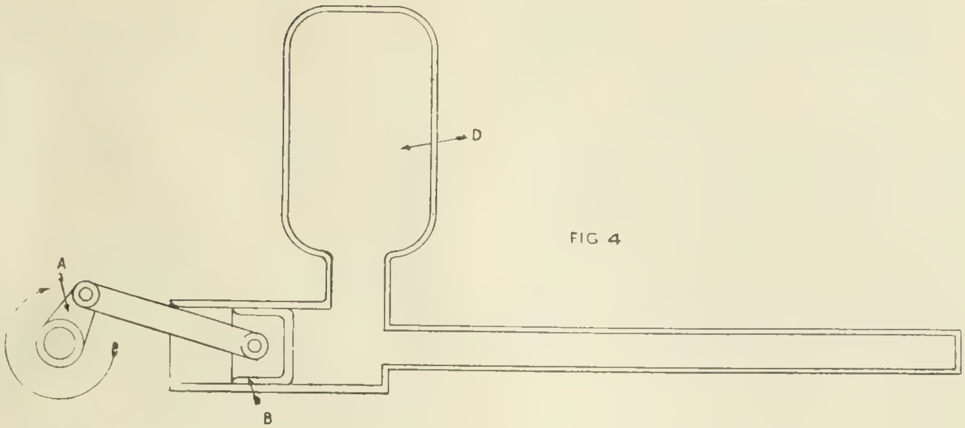

FIG 4

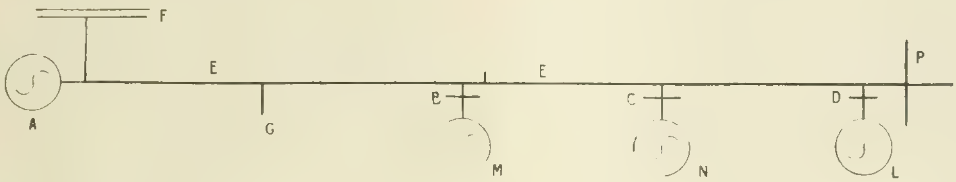

FIG 5

pressure is always zero, no energy can be taken up by the motor, and the stationary wave will persist in the whole length of the pipe.

If the motor be connected at any intermediate point, part of the energy will be taken up by the motor, while the stationary wave will persist, but will be of reduced amplitude between the generator A and the motor. The state of the liquid between the generator A and the motor may be considered as the resultant of two superposed waves; one a stationary wave, and the other a travelling wave of flowing energy.

Assume now that the motor L is not capable of taking up all the energy which can be transmitted to the line by the generator A; then we shall have superposed in the pipe a system of stationary waves and a system of waves travelling along the pipe, so that there will be no point in the pipe at which the variation of pressure will always be zero; consequently a motor connected at any point of the pipe will be able to take up and utilize a portion of the energy which is transmitted to the line.

We see, therefore, that if we have a number of motors all connected to the line, every one of them will be able to take some energy and do some useful work. It is only when no energy is being utilized that points at which the variation of pressure is permanently zero can exist.

In the next article will be given a full description of the application of the wave-transmission principle in practice, with particulars of the wave-generator, means of transmission, and method of applying the power to rock-drills and other tools.

(To be concluded).

Sir John Cass Technical Institute.—The annual distribution of prizes was held on February 10, the ceremony being performed by Sir Frederick Black, president of the Institution of Petroleum Technologists. Sir Frederick subsequently delivered an address on "Liquid Fuel in Peace and War."

Robert Peele, author of "Compressed Air Plant" and "The Mining Engineers' Handbook," is the subject of an appreciative notice in the *Engineering and Mining Journal* for January 15. Mr. Peele graduated at the Columbia School of Mines, New York, in 1883, and for several years thereafter was engaged in mining and metallurgical work in Colorado, Arizona, and New Mexico. Afterwards he went to Colombia and Dutch Guiana, and subsequently, from 1890 to 1892, he was in Peru and Bolivia for the Peruvian Corporation. In the latter year he became assistant professor of mining in the Columbia School of Mines, but retained his professional business, being a member of the firm of Olcott, Corning, & Peele. In 1910 he visited the Rand and the diamond mines at Kimberley.

THE PHYSICAL BASES OF TIN-DRESSING.

By R. T. HANCOCK, Assoc.Inst.M.M.

INTRODUCTION.—To-day the wet method of dressing by which tin ores are concentrated is little more than an interesting survival. All other ores of importance (wolfram is not important at present) are, or can be, successfully treated by smelting, chemical, or flotation processes. And the Cornish industry is looking forward hopefully to the day when one of these will be made applicable to its own problems, and is altogether indisposed to countenance investigation into the methods it already practices. With a personal belief that this day is more distant than those whose thoughts are fathered by their wishes are inclined to believe, I have collected the following notes, and hope that something will be found among them of service to those who are now engaged in guiding the industry through a particularly critical period.

Anyone who is engaged in dressing ores should have a clear idea what his object really is. The mere percentage recovery of the metal content means nothing; this can best be secured by avoiding dressing altogether. Metallurgically, the efficiency of the result of an ore-dressing operation is expressed by the difference between the percentage recovery of the original metal or mineral content and the percentage "recovery," or retention in the concentrate, of the waste matter or gangue present in the original ore. Economically, efficiency is reckoned in the same way, but here the retention in the concentrate of a given percentage of the original waste generally more than counterbalances the recovery of a similar percentage of metal or mineral, and so the percentage retention of the waste must be multiplied by a factor depending for magnitude on the prevailing economic conditions before deducting it from the percentage recovery of metal or mineral in order to correctly express the economic efficiency. In this paper metallurgical efficiency will alone be considered.

ACTION OF A FLOWING STREAM ON SOLID PARTICLES.—The late Dr. Grove K. Gilbert, in "Transportation of Debris by Running Water" (Professional Paper No. 86 of the United States Geological Survey), distinguished two main sets of conditions of transport:

(1) Over a smooth surface. (Flume traction).

(2) Over a bed of the deposited solids. (Stream traction).

The first condition is found on the rag frame and on the Frue vanner, and the second on the buddle.

A transitional stage may be recognized where the load is a little too great for complete transport over a smooth surface, so that part settles out and the condition changes to transport over a deposited bed. The capacity of water to transport solids is much the greater over a smooth surface, though decreasingly so as the particles are smaller, and if part of the load deposits it will build up the bed till a steeper grade is established. From the point of view of capacity of machines, a consistency of pulp such that deposit does not take place would appear preferable. A tendency to deposit is responsible for the formation of patches of settled material which may lead to channelling if flow is continued. Initially these patches are due to rhythm in the flow of the water. In stream traction they are represented by dunes, and with this mode of traction the formation of dunes was found to be at a minimum on slopes of approximately 1% grade, the region being little affected by changes in other conditions. No similar observation on flume traction is recorded.

The sizes of sand used by Gilbert ranged from 60 mesh to coarse gravel, and the quantities of water from 0·141 to 1·119 cu. ft. per second per foot of width. The smaller of these quantities is equivalent to 528 lb. of water per foot of width per minute, which is enormously in excess of anything used in ore-dressing. On the other hand the slopes seldom exceeded 2%. For the treatment of slimes on fixed slime tables, Professor R. H. Richards proposes 2 lb. of water per minute per foot of width, and Professor S. J. Truscott, reproducing on an experimental frame the conditions prevailing in Cornish practice, used practically this same quantity. Nevertheless, it would appear legitimate to apply some of Gilbert's conclusions to the study of slime treatment.

In Gilbert's experiments on stream traction, the sized sand was caused to flow over a bed formed by the deposit of that sand itself. Resistance to transport—indicated by low capacity of the flowing water for sand—appears to be at a maximum when the bed thus corresponds in roughness to the size of the moving particles. Over a bed composed of smaller grains, larger particles move more rapidly. The same thing applies with any degree of roughness of sur-

face however arising. Yet experiments conducted at the Utah School of Mines, and recorded in *Mines and Minerals* for February, 1909, showed a larger capacity for 10 to 30 mesh limestone tailings and 30 to 40 mesh pyrites in launders lined with linoleum or of wood than when the launders were bottomed with plate-glass. Large quantities of water were used (from 10 to 60 lb. per inch of width per minute), and the observation is probably connected with the fact that at velocities exceeding about 1 ft. per second, the velocities of the flow of water in a wooden pipe (planed) is much greater than in a glass pipe of the same diameter and on the same gradient. Thus with pipes 4 ft. in diameter and lying on a 1% slope the velocity in the wooden pipe would be 15 ft. per second against 11 ft. per second in the glass pipes. The laws of flow change below the critical velocity of about 1 ft. per second, and it is not known if the same is true at lesser velocities. The subject of the inherent properties of surfaces of different bodies, which manifest themselves as above and in other ways, is of special interest to the investigator, but can be no more than referred to here.

In Gilbert's experiments on stream traction (deposited bed), the capacity of the water as a carrier of debris increased regularly as the debris was finer. With flume traction (smooth bed), on the other hand, there might be sizes too large to roll at all, but for the next smaller capacity was high and decreased as size of particle decreased until a minimum was reached corresponding to a critical size varying with the flow conditions, after which further decrease in particle size was attended by a steady increase in capacity. (See Fig. 1). It is a matter of common observation that in a sluice bottomed with sand, coarse particles travel down faster than the sand grains over which they roll, and that the larger outstrip the smaller. On the other hand, particles small enough to remain in suspension travel as rapidly as the water itself.

The travel of particles over a bed or surface is mainly by rolling for the largest sizes and suspension for the very smallest, these two systems grading into each other through a type of motion called by Gilbert "saltation," in which the particles both roll and leap, the latter predominatingly as the particles are smaller. Saltation is the motion of the majority of the particles.

The mathematical treatment of the behaviour of particles which roll is discussed by Professor Henry Louis in "The Dressing of Minerals," and elaborated by St. Rainer in the issues of *Oesterreichische Zeitschrift für Berg- und Hüttenwesen* of February 4 and 11, 1905.

As the velocity of a current decreases with depth (a generalization, but perhaps true of all currents carrying loads), any particle in suspension is subjected to a force which causes it to move into a slower-moving stratum, and consequently to sink. The greater the rate of change of velocity with depth, the greater this force. Tea-leaves seek the centre of the cup on stirring, and not the outer margin where centrifugal force would naturally place them. Thus a suspended particle will sink to the

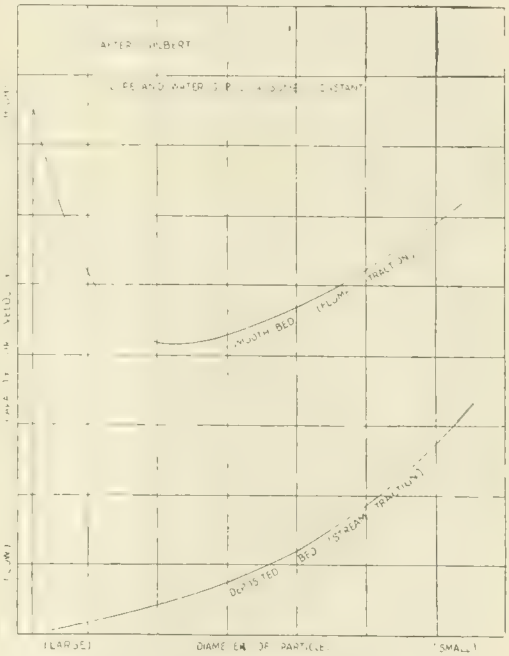

FIG. 1.

bottom more rapidly than it would if acted upon by gravity alone.

CONCENTRATION CONDITIONED BY MINIMUM VELOCITY.—Only a limited number of experiments were conducted by Gilbert on flume traction, and, under the particular conditions employed, minimum capacity or velocity was found associated with a coarse sand. Evidently the minimum will occur where the particles are too small to respond freely to the couple which produces rolling, and yet too large to pass freely into suspension. Stream conditions favouring suspension will cause the size of sand characterized by minimum velocity to be large. With any stream conditions there must be a particular size of particle which will travel slower in that stream than any larger or smaller particle of similar shape. As to

what this size may be there is little available evidence.

The late J. J. Beringer (Transactions Institution of Mining and Metallurgy, Vol. xxiv, p. 411) gives the following estimate of the sizes of particles in concentrates based on microscopic examination:

Slime product	from 5 to 45 μ	Average 25 μ
Vanner product	,, 25 ,, 95 μ	,, 50 μ

one micron (μ) = 0·001 mm.

In the same contribution (The Physical Condition of Cassiterite in Cornish Mill Products) he mentioned a case where vanner tailings from the calcined concentrate were returned to the vanner for treatment. "The second concentrate on being examined under the microscope showed distinctly two different sizes, a coarser portion with grains measuring from 50 to 75 μ, and a finer portion with grains measuring from 10 to 15 μ, a fair proportion being of 10 μ size."

I regard this as strong evidence that the first treatment abstracted particles of a size ranging about a definite mean magnitude, say 40 μ, and the second treatment saved particles on the margins of this range which had escaped under the first treatment more or less by accident. There are those who believe that the vanner treatment of unclassified pulp saves fine slime tin which would not be caught otherwise. The above figures might be claimed to support such a theory, but it is in the highest degree unlikely that such fine particles would form a distinct group with practical absence of particles ranging from their size to those constituting the remainder of the concentrate. It may be added that Mr. H. W. Hutchin has sought for evidence of such extra saving, and failed to find it.

I am strongly of opinion that with any given set of conditions the sizes of the particles of mineral in the concentrate produced will be grouped about a definite mean magnitude, and the mineral in the tailing will be predominantly composed of particles of a size on one side or the other (or both) of this range. The concentrate particles, both mineral and waste, will be those which travel most slowly under the actual flow conditions.

Where there is a marked difference in the specific gravities of mineral and gangue, as with tin ores, the tendency to roll and the reluctance to pass into suspension will extend further into the region of small sizes with the cassiterite than with the gangue, and consequently the gangue found in a concentrate would consist of larger particles than the accompanying cassiterite. A grading analysis of such concentrate would show the values mainly in the finer sizes. But as in an elutriation analysis the finest material is unavoidably reported as of lower grade than the actual sorting by screens would show, this feature is not usually conspicuous in published instances of grading analyses so made. Moreover, such concentrates as have been examined in this manner have usually been produced in an endeavour to obtain a low-grade tailing rather than effectively concentrate, and so do not show the full effect of the above-noted tendency. Further, the grading analysis of a concentrate or tailing is profoundly modified by the treatment history of the product from which it is originally derived. Consequently there are no data in existence which indicate what particular sizes of crushed quartz (say) travel slowest under given conditions of slope and water-supply. A particular size might still remain associated with minimum velocity if slope were changed and water-supply suitably modified.

Mr. J. A. Davis (*Engineering and Mining Journal*, November 9, 1908) gives the formula which follows for the best dressing conditions in separating closely-classified galena from quartz on a glass frame, as determined in the laboratories of the Massachusetts Institute of Technology:

$$\text{Slope in inches per ft.} \quad \frac{1}{8}\left(\frac{275-50\sqrt{\frac{1}{d}}}{W}+\frac{10}{\sqrt{\frac{1}{d}}}\right)$$

where d = average diameter of quartz particle in millimetres, and W = lb. water per foot of width per minute.

It was found that the classification had been carried a good deal further than was necessary for good results, and that a large number of classified products from an original pulp were not necessary. No determinations were made on sizes smaller than about 180 mesh, and the formula is so empiric as to make its extension to slimes very unreliable. But it is of interest to observe that with 300 mesh material two lb. of water per foot of width per minute would call for a slope of 2⅛ in. per foot.

With a feed in which the values are regularly distributed throughout the range of sizes, variations in flow conditions, within such as are practicable for dressing, would have little effect on the efficiency of concentration resulting. The actual particles of mineral (say cassiterite) saved under one set of conditions might be quite different from those saved under another, and the gangue particles which accompanied them different individuals in either case, but the resulting proportion of mineral to gangue is not necessarily modified. Perhaps as a consequence of this it is not easy,

in the many cases instanced by Truscott in his paper on "Slime Treatment on Cornish Frames," to say definitely that a given set of conditions of flow produces better results than another. When there is a difference it can usually be as well ascribed to other causes. Truscott in fact decides that the finer the material the less the inclination should be, while Richards comes to the exactly opposite conclusion as the result of his own experiments, but admits that he does not find any rule to be followed in practice. Where, on the other hand, the distribution of the values is irregular in the feed, or a classified product is being treated, a particular set of conditions will doubtless give better results than any other, but such conditions must be found by trial.

In any ordinary ore-pulp, and under any set of conditions in reason, there will always be certain particles of gangue which will behave exactly as do certain particles of valuable mineral, and will accompany them either into the concentrate or the tailing. Even if it were possible to break up this grouping by specially adjusting conditions, it would only mean the substitution of one group for another with little effect on the final result.

Although it has been implied that the particles forming the concentrate will be those having the slowest travelling rate under the prevailing conditions, it must be borne in mind that the dominant size of the particles in the concentrate is a function, not only of the travelling rate, but of the distribution of the various sizes through the original pulp. Thus if there is a group adjoining the slowest travelling group, which forms a comparatively large percentage of the pulp, that group is likely to predominate in the concentrate. A usual practice is to re-treat tailings under different conditions of slope. A shift of the range of size of saveable cassiterite may now be expected, and sizes saved which previously escaped, but it is evident that an adjacent group of barren material will now be present which was rejected in the first treatment, and this is likely to be thrown into the second concentrate by the very changes which made that collection possible. Consequently the re-treatment of tailings in this way is not a very satisfactory process. To repeat the original treatment on a tailing product serves its most useful purpose when the original treatment was not carried to completion. Thus in the case instanced by Beringer, the first vanner concentrate was produced at an efficiency of 62·5% with a recovery of 78%, while the concentrate produced by re-treatment of its tailing was at an efficiency of 3·3% with a further recovery of 5·5%.

It becomes evident that effective concentration is much more dependent on the initial physical condition of the feed than on any adjustment of dressing conditions.

Granting that the effective concentration of ores by the flow of water over smooth surfaces in thin films is dependent for success on the fact that under these conditions certain particles travel more slowly than others, then it necessarily follows that on a frame fed at a regular rate and with a normal feed there will result an accumulation of such particles on the surface, such accumulation not resulting from their actual arrest or settlement, but simply from their slower motion. As the feed period is prolonged these particles continue to progress down the frame, and after a certain time reach its lower edge and commence to pass into the tailing. During the feed period the assay of the escaping tailing increases, not necessarily regularly, for that depends on the physical condition of the feed, and at the moment when the first fed of the slowest travelling particles passes the lower edge, the assay of the tailing increment then escaping attains the assay of the feed. Naturally it can never exceed it, but will remain at the same figure if feed is further prolonged. During the time that each increment of tailing passing the lower edge has a lower assay than the feed, the efficiency of concentration is increasing and attains its maximum at the moment when the former attains the assay of the feed, decreasing if feed is further prolonged. Given regular feeding and flow it follows that the assay of any strip taken at right angles to the flow when maximum efficiency is attained will be the same as that of any other strip. The enrichment thus attained will be the maximum under the conditions employed, and if there is one set of conditions better suited to the ore than another, a determination of the enrichments attained will give a pretty good guide to its selection. The actual efficiency attainable cannot be ascertained unless the feed is interrupted at the critical moment, to discover which it will be necessary to sample successive tailing increments.

The best length of feed period will vary directly with the length of the frame, and with any given pulp and dressing conditions there is a particular feed period best suited to a given length, and vice versa. The condition of an even assay all down the frame is one that is attained from the feed-end downwards, and when half the correct period has elapsed, the upper half of the frame should assay the same all over, the area extending as feed is prolonged

until the whole frame is so covered. Terminal conditions, especially at the feed end where the feed may come on to the frame with an acquired velocity different from that generally prevailing on the surface, are left out of present consideration. When the lowest part of the frame is thus covered, the assay of the material escaping just below is nevertheless not higher than that of the original feed. In other words, the assay of the material flowing across a particular narrow strip is an altogether different thing from the assay of the material on that strip considered as suddenly arrested there. This is not an altogether easy thing to realize. The ratio of the "arrested" assay to the "flowing" assay may be quite high, and is a measure of the tractability of the ore. It may be that this ratio is preserved on the lower part of the frame before the feed period is completed, but this point is of little more than speculative interest.

In the experiments which were carried out at Great Falls, Montana, described in the Transactions of the American Institute of Mining Engineers for 1913, with the object of devising the best means of saving copper slimes, the conditions finally adopted were such that the assay of the concentrate collected on the round tables was the same from top to bottom, with the exception of a strip at the feed-end. It is interesting to note that this research led to the installation of a system of slime treatment at Anaconda which paid for the erection of the necessary plant in two months, and thereafter saved $1,250,000 per annum.

PROFESSOR TRUSCOTT'S RESEARCHES.—In the paper already referred to, a number of experiments are described where the distribution of the concentrate down the frame was determined by dividing it into five sections at right angles to the flow, and assaying and weighing the concentrate on each section. Employing the data obtained, if the reciprocals of the cumulative enrichment ratios be plotted against the cumulative percentage concentrations, it is found that the loci corresponding to the lower sections fall closely along a straight line. The first section, sometimes the first two, and in one case the first three, do not conform to this arrangement. I find strong confirmation of the views I have expressed above in these facts. The lower sections are those below the limit of maximum enrichment, and the graphs confirm my view that if feed were prolonged there would be no sections conforming to the law indicated by this straight line, but that the plotted points corresponding to all the sections would lie along a line parallel to the percentage concentration axis. Fig. 2 shows the plot of two such experiments on a wooden surface with auxiliary washing, all the plots, whether on wood surfaces, plate or fluted glass, and with or without washing, being of the same general character. All the experiments having been conducted with the same length of feed-period, no direct evidence of the effect of a longer feed-period is available, but an increase in the slope would have a similar effect, and it will be observed that this is to shorten the length of the line representing the lower sections, the inference being that with a

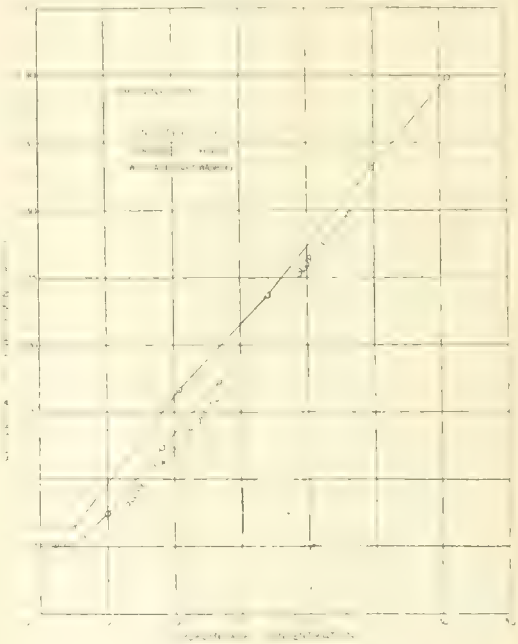

FIG. 2.

sufficiently long period of feed, or one duly proportioned to the gradient and the length of the frame, this sloping line would disappear altogether, leaving only the short horizontal portion of the graph. If feed were unduly prolonged, this horizontal line itself would shorten. Two different laws, then, are desirable from a study of the graphs, the first and most conspicuous being that on the lower sectons of a frame on which concentration has not been pushed to maximum efficiency, the relation of enrichment ratio (ER) to concentration (C), both cumulative, is expressed by a formula of the type

$$\frac{1}{ER} = a + bC$$

the second being that on those sections where maximum efficiency has been attained the

cumulative enrichment is equal to a constant.

This last law, which is demanded by the theory of concentration outlined above, is not very strongly supported by the different graphs, possibly because in the majority of cases concentration has not been pushed anything like far enough to show its application clearly, but in the one case observed where concentration has proceeded furthest, it may fairly be said that the first three sections out of the five conform to the required law. Further support is derived from the Anaconda researches already mentioned.

The first law, the law of the lower sections, may be written :

$$R = \frac{C}{a+bC}$$

which is the equation of a hyperbola. A straight line equation can also be derived connecting cumulative percentage recovery (R) with cumulative enrichment ratio.

A law, or mathematical formula, expressing the relation of recovery to concentration has long been sought, and its discovery here is therefore of some interest, but of very little practical importance, as it merely serves to express the relation existing on a frame where flow has been arrested, and arrested too soon. What is of real importance is the assay of the flowing pulp, and not that of the arrested pulp.

The data indicate that under the conditions and with the particular conditions of flow given, a shorter frame would have given better technical results, and on these grounds Truscott suggests that the present length of the Cornish frame should be diminished by half in order to secure the improved efficiency characteristic of the upper sections. But actually no guide to the appropriate length can be found in the figures obtained, as these relate only to the arrested concentrate, and give no clue to what might have been the assay of the flowing pulp at the different points. It is where the flowing pulp has the same assay as the feed that determines the optimum length of frame, and not the assay of the arrested concentrate on any particular section. With the feed conditions given, the data, if obtainable, would point to an even more drastic shortening of the standard frame than Truscott proposes.

In a supplementary paper Truscott describes experiments carried out at Dolcoath where the ordinary 6 ft. 6 in. frame was run against a frame divided into two lengths of 3 ft. each with arrangements for collecting the upper and lower concentrates separately. These experiments were carried out under ordinary mill conditions and are therefore of special interest. It was considered that the results demonstrated the general superiority of the 3 ft. frame, but I do not altogether concur after a detailed examination of the figures.

Frame length.	Tests.	Slope per ft.	Feed period.	% Recovery.	% Concentration.	Enrichment.	% Efficiency.
6 ft. 6 in.	6	1·25 in.	2·7 min.	71·2	63·9	1·113	7.2
Do	2	1·50 in	4·4 min.	61·7	40 3	1·535	21·4
Do	1	1 50 in	5 0 min.		—	—	24·1
3 ft.	8	1 50 in.	5·6 min.	4 30	1·50	2·87	28·0

Increased steepness of gradient, as it causes a general speeding-up of all the particles, is similar in effect to a longer period of feed.

The above figures seem to indicate that with equal feed periods and slopes the technical results would have been equal on both types of frames, and further that a longer period of feed than was employed in any case would have given better results still.

Truscott claims that the adoption of his suggestion to cut down the length of the frames would enable an effect styled "rapid enrichment" to be attained, better technical results being obtainable on half the present area of frames employed, the remaining area becoming available for re-treatment of the tailings from rapid enrichment. This is undoubtedly true, but as far as better technical results are concerned, it seems probable that these could equally be secured on the present frames by increasing the length of the feed period. It is difficult to see any justification for the present practice of gradual enrichment, though one usually exists for empirical methods which have been evolved in Cornwall through the experience of centuries, and I am inclined to regard such practices with considerable respect, but since it is comparatively yesterday that accurate methods of ascertaining the true contents of an ore or tailing were evolved, it is perhaps permissible to review them in a fresh light. A frame is a machine, and it is difficult to justify the employment of a machine at far below its maximum efficiency.

Two sets of experiments were conducted by Truscott on a laboratory scale to ascertain whether the customary practice of obtaining the final concentrate in three stages possessed any marked advantage over his suggested method of obtaining it at one operation. The first of these was tried on slime samples from Dolcoath and South Crofty. The similarity of the results was remarkable, the efficiency of the final result of gradual enrichment being 31·3%, of rapid enrichment 30·6%, and of rapid enrichment at a double rate of feed 28·7%.

In the second set original mine-ore was ground to the condition of slime. Again the

results showed great similarity, the average of the four ores giving an efficiency of 65·4% with gradual enrichment, 65·8% with rapid enrichment, and 64·3% with rapid enrichment at a double rate of feed. Calculating the figures for the individual ores, Tresavean ore gave an efficiency of 64·3% with all three methods, so it is evident that no importance is to be attached to such slight differences as were shown, but that these were only such as might easily arise in experimental determinations.

Further experiments were conducted on the tailings resulting from rapid enrichment and from rapid enrichment at a double rate of feed, but not on the tailings from gradual enrichment. A further recovery was effected at low efficiency rates, and a claim was based on the figures for increased recovery in the form of saleable concentrate as a result of the adoption of the principle of rapid enrichment, but it is evident, if the weights and assays of the three tailings are calculated and compared, that their composition and physical state could not have varied very much whichever of the three processes was adopted, and a similar further recovery might have resulted from the re-treatment of the combined tailings from gradual enrichment, so that rapid enrichment does not necessarily render possible a higher recovery of saleable concentrate than if the present system of gradual enrichment were employed. Any advantage of rapid enrichment lies in the more efficient employment of the dressing surfaces, lowering the dressing cost, and so making it possible to chase values further.

A method of calculating the final recovery in the form of saleable concentrate was used in the paper, based on the result of a single stage of treatment, and it purported to show that the reduction of the mine-ore to slime in the first instance and its treatment on frames in the manner described might produce better results than coarser crushing and the preliminary classification of the pulp into sands, fine sands, and slimes, for individual treatment. If the basis of this calculation be examined, which is that the loss suffered by a medium-grade concentrate in being raised to merchantable grade varies inversely with its assay, it is found to be the same as stating that the tailing removed at every subsequent stage of dressing will assay the same as the original battery feed, a most unlikely series of events.

Returning to a consideration of the Dolcoath experiments, a striking feature is that, contrary to what might be expected, the tailing assays were actually lower with longer periods of feed. Thus on the standard frame with 1·25 in. slope and a feed period of 2·7 min. the tailing assay was 6·4 lb., with 1·5 in. slope and 4·4 min. feed it was 6·45 lb., and on the double frame (combining both concentrates to get the equivalent length to a standard frame) with a 1·5 in. slope and 5·6 min. feed it was 5 lb. These figures require to be corrected for differences in the average assays of the respective feeds, and allowing for these, the figures are in the ratios 0·80 : 0·64 : 0·60. The probable explanation is that the first tailings to escape are rich slimes, which naturally continue to escape during the whole operation, but their effect becomes masked by the later arrival of poor sands. If these sands are retained on the frame through short duration of the feed period, the whole operation suffers in efficiency.

In frame treatment a pulp having the values mainly associated with a certain range of size of particles will require for best results altogether different dressing conditions from those best suited to a pulp having the values mainly associated with a different range of sizes. Any pulp may be considered as consisting of a mixture of two or more such pulps, all being treated together under conditions which are more or less a compromise. It is useful to regard certain pulps from this point of view, particularly those consisting of tailings where the operation producing them has taken a big bite out of a certain range of sizes and left the principal values in the tailings on either side of this range, such as the vanner tailings instanced by Beringer, the conditions in this respect recorded by him being probably true of vanner tailings in general. An attempt to adjust the dressing conditions to save the faster travelling particles of cassiterite means that scarcely any effective concentration of the slower travelling fraction is obtained, yet this seems to be what is generally done. The escaping tailing increment, mainly slime, quickly attains the assay of this rapidly moving portion of the pulp, and this may be high. If feed is now stopped, the concentrate arrested on the lower portion of the frame may well be of lower assay than the whole of the tailing which has escaped, as Truscott found with an experiment on Dolcoath No. 4, a typical specimen of this class of pulp. Further experiments were conducted on this pulp to determine whether a longer period of feed might give better results; as the experiments were designed to reproduce on a flat frame the conditions obtainable on a round table by slowing down its period of revolution, a washing period was given, and this was longer with longer duration of feed. An unfortunate arithmetical error was responsible for the de-

cision that the shorter period was best, but the following observation is a better record of the facts: "The appearances suggest that owing to the relatively high inclination much of the very fine tin goes direct to the tailing, but that if discard were continued the next material to go would be poor sand."

Truscott's experiments on whole pulps, that is, on pulps which represent the whole battery product, such as those on his synthetic ore and on the mill-ores ground to the condition of slime, indicate that the maximum enrichment obtainable on frames without washing will be about 14·3 associated with a concentration to 5%, a recovery of 71·6%, and consequently an efficiency of 66·6%. Any attempt to push enrichment further by washing seems to be at the expense of efficiency. These figures, and in particular the efficiency, are dependent on the physical condition of the ore, and not on its original assay. They demand that the cassiterite should have been practically freed from its matrix. The richer the original ore, the richer will be the concentrate and tailing in direct proportion. With a 1% ore, the concentrate would assay 320 lb. per ton, and the tailing 6·7 lb.

Instances of the frame treatment of thickened overflow from classifiers taking the original mill-pulp are not sufficiently numerous for close figuring, but indicate, in the case of the Tincroft slime, an efficiency of possibly 50%, with a 4 lb. tailing, the latter low figure being due to original feed only assaying about a half per cent. This on what might be described as a classified feed.

SHAKING TABLES.—Such figures as are available relating to the performances of tables of the Wilfley type and Frue vanners, in the treatment of unclassified or original pulp, do not indicate that a higher efficiency is attainable by these machines than on flat frames. Messrs. Cox, Porter, and Gibbon ("Mineral Industry," 1911) obtained figures which I believe relate to the performances of a Wilfley on copper ore, though my notes are not complete in this respect, which show that the efficiency with which the natural ore was treated was 64·4%, the mean efficiency of treating this ore in separate lots graded by screening being 63·9%, and of grading the lots by classification 66·7%. In obtaining these averages it is assumed that each of the six lots obtained by each grading process were of equal weight. The minus 100-mesh lot obtained by screening was treated at an efficiency of 48·7%, the average of the remainder being 67·3%, while the finest product of classification was treated at an efficiency of 51·2%, the average of the remainder being 69·8%. An advantage of shaking-tables lies in their greater capacity per unit of floor area. Thus the Frue vanner will handle one ton per foot of width in 24 hours, a flat frame requiring six feet of width to treat this tonnage. The effect of shortening the frame length, increasing the gradient, and feeding a larger quantity of a thicker pulp than usual, all of which appear feasible, would be to place the two appliances on a more equal footing as regards area capacity.

WASHING.—The general question of washing remains to be discussed. Washing is not practised on flat frames, and the complications which its employment would entail militate against its adoption unless a very marked advantage can be demonstrated. Where concentration on a flat frame has not been carried to the point of maximum efficiency, washing is somewhat similar in effect to a prolongation of the feed period, and is therefore commonly attended by improved technical results. Washing will in fact improve the technical result just so long as the tailing increments escaping during the washing period do not attain the assay of the feed. Where the feed period has been so prolonged that maximum technical efficiency has been obtained it is difficult to see that washing can further increase this, and certainly it has not been demonstrated. Nor has it been demonstrated that a higher efficiency is attainable by auxiliary washing than by the selection of a suitable period of feed.

Round frames, on the other hand, are always provided with arrangements for washing. The concentrate from these goes customarily direct to the calciner, and the function of washing is here to increase the enrichment, even if a slight loss in metallurgical efficiency is thereby incurred. If it is attempted, by employing the principle of rapid enrichment in the flat-frame treatment of slimes, to obtain at one operation a concentrate sufficiently high-grade to send to the calciner, some means of washing might be advantageously employed in the same way.

CLASSIFICATION.—The term classification is reserved to express sizing by the employment of rising hydraulic currents and covers a rather wide range of effects, from the mere division of a mill-feed into sands and slimes, to the operation of a multiple-spigot classifier of the latest type.

Cornish practice has come in for a good deal of outside and not always too well-informed criticism on account of the small part which classification supposedly plays in it, particularly that classification direct from the stamp

which some, who have not sufficiently taken into account the nature of the subsequent processes, consider essential to good work.

Granted that the concentrate produced by a frame, vanner, or other smooth surface, consists essentially of finer cassiterite associated with coarser waste, its becomes evident that classification, by throwing together fine cassiterite and coarse waste, is the deliberate preparation of the worst possible kind of material for treatment on a smooth surface. This arises from the existence of a minimum value on Gilbert's curve of velocities plotted against particle diameters treated under flume (smooth surface) conditions. A coarse particle of quartz may occupy a position on the descending leg of the curve which will indicate the same velocity as possessed by a small particle of cassiterite on the rising leg. It is possible, of course, that if the classified product consisted only of two such groups, one of quartz and the other of cassiterite, a modification of the flow conditions might be made which would place the cassiterite in the minimum velocity position, but hardly anything is known of the modifying effect of such changes, except in the vaguest way, and extreme niceties of adjustment cannot be secured and preserved in practice. The more perfect the classification, the more likely it is to be attended by ill results, and the practice of treating the whole battery pulp on vanners without classification is abundantly justified. It is possible that the dilution of the slime feed consequent to classification also has an injurious effect. Mr. J. Bland (*Engineering and Mining Journal*, June 28, 1919) has published figures showing that on a Deister No. 3 slime table the concentrate contained 40·2% of minus 1/2,000 in. wolfram when the consistency of the pulp was two and a half parts by weight of water to one of solids, whereas none of this fine wolfram was recovered when the consistency was twelve to one. The quality of the concentrate did not suffer, but the capacity of the table was reduced as thicker pulps were treated, and the percentage recovery and extent of concentration are not stated.

RECOVERIES BY TIN STREAMERS.—As the amount of concentrate recovered in a saleable condition forms so small a portion of the whole mill-feed, the total tailings produced by the various operations of the mill, if put together finally, would reproduce very closely in physical condition the original feed as it came from the stamps, allowance being made for supplementary crushing undergone by some fractions. The intractability characteristic of the tailings of a particular machine would be found to have largely disappeared if such a combined tailing were put through a mill again, and the preliminary stage of its treatment might be attended with something approaching the high degree of metallurgical efficiency characteristic of an original pulp, due allowance being made for the fact that a much larger fraction of the cassiterite in the pulp would not be free, but combined as chats. The foregoing seems a quite sufficient explanation of the fact that streamers make satisfactory recoveries of tin which has resisted saving in the original mills. It is not in the least necessary to drag in "colloids" or imagine that the cassiterite undergoes some physico-chemical change in its passage down the Red River.

The intractable condition of a tailing can also be modified by re-crushing before re-treatment, which smoothes down the asperities of the grading analysis, and reproduces a pulp of a more normal type. This alteration of the grading analysis is an advantage additional to the liberation of previously attached cassiterite, and as re-grinding is obviously limited to coarse products, is an argument in favour of preliminary coarse crushing.

THE BUDDLE.—So far the conditions discussed have been those prevailing on a smooth concentrating surface. Those which obtain on a buddle are quite different, for the reason that the flow conditions are now more those of the stream (deposited bed) traction of Gilbert. Yet here also the influence of a minimum value in the velocity curve has not altogether disappeared, but persists for a reason which has been left undiscussed: that over a surface which is not perfectly smooth, the maximum retarding effect on a moving particle is found on a surface whose roughness corresponds in grain to the size of the particle. The behaviour of the particle is of course not conditioned by this cause alone, but this is the principal one. The roughness of the surface on the buddle increases toward the discharge periphery, and every particle finds an appropriate resting-place among its fellows. There is nothing in the theory that cassiterite tends to catch cassiterite; size is most important in deciding where any individual comes to rest, and the influence of specific gravity seems to be secondary. Some tests made by me on Nigerian concentrate obtained by a process akin to buddling showed that the finer grained fraction separable by screening was of noticeably lower grade than the coarser, the specific gravity of the waste mineral being 4·7 to 5, proving that a slight diminution in size caused particles of lighter material to hang back among the denser cassiterite.

It is much to be regretted that no data are in existence on the performance of buddles comparable to those obtained by Truscott for frames; but I am inclined to think that such data would establish that the buddling of mixed (unclassified) sizes causes the cassiterite to persist through the buddle products in a way that might be prevented by feeding the buddle with a classified pulp.

The operation of panning is in many ways comparable to buddling in that the coarser particles tend to roll across the mass deposited in the bottom of the pan and escape, the resulting concentrate being one of finer grain as well as of denser material. So that certain figures published by Professor Edwin Edser in a recent communication to the Institution of Mining and Metallurgy may be usefully studied, although they were given solely with a view to the elucidation of a law of concentration connecting recovery with enrichment. The material tested was a sample from a Cornish river deposit containing waste cassiterite from tin-dressing operations. This waste was screened through 80-mesh and the undersize elutriated into seven products by the method described by Mr. Thomas Crook in the appendix to Hatch and Rastall's "Petrology of the Sedimentary Rocks." This method would doubtless give products obtained under free-settling conditions, and not so perfectly graded as those obtainable with a classifier working under hindered-settling conditions, yet, as a laboratory product, perhaps more perfectly classified than would result from the operation of a hindered-settling classifier on a practical scale.

The two finest sizes proved unsuitable for panning (but not for framing), and the remaining five, 77·6% of the total, were panned individually to an average concentration of 15% sampled and assayed, and further panned down to an average concentration of 1·3 per cent.

First stage of concentration:

Mesh	Weight	Recovery	Concentration	Efficiency	Tailings lb.
A −2,500	13·2				
B −1,800+2,500	9·2				
C −1,000+1,800	12·6	0·808	0·129	0·679	4·0
D − 570+1,000	7·7	0·840	0·162	0·678	2·7
E − 300+ 570	8·7	0·748	0·216	0·532	4·0
F − 200+ 300	36·2	0·684	0·125	0·559	5·1
G − 80+ 200	12·4	0·777	0·215	0·562	3·6
Totals and averages	100·0	0·745	0·154	0·591	4·3

Thus from an original feed assaying 14·4 lb. Sn per ton, a recovery of 74·5% has been effected in a concentrate assaying 70 lb. per ton, with a concentration to 15·4% of the original weight, the tailings assaying 4·3 lb.

The second concentration of the concentrates obtained above gave the following results, reckoning from the original feed:

	Recovery	Concentration	Efficiency	Tailings lb.
C	0·656	0·014	0·642	5·1
D	0·660	0·014	0·645	4·0
E	0·590	0·020	0·570	5·2
F	0·437	0·008	0·429	8·1
G	0·585	0·018	0·567	5·3
Totals and averages	0·563	0·013	0·550	6·4

Thus the combined result of the two stages of concentration was to produce a concentrate assaying 605 lb. per ton, with a recovery of 56·3% of the original contents in a concentration to 1·3%, with a combined final tailing assaying 6·4 lb. per ton.

The combined tailings made in producing the second concentration from the first assayed 21 lb. per ton, showing that the concentration was pushed too far in the second stage for the best metallurgical result. This was particularly the case with product F, the second tailing of which ran 31 lb. per ton.

It is my opinion that if buddles were fed with a well-classified feed from a multiple-spigot hindered-settling classifier, something closely approaching the foregoing results could be duplicated in practice. Such a result, for instance, on a 1% ore, as 1·5 tons of 500 lb. Sn concentrate ready for the calciner, 13·5 tons of 85 lb. middling for re-treatment, and 85 tons of 4 lb. tailing for final rejection. The existence of this comparatively large tonnage of middlings would be due to unavoidable imperfections in classification and to the existence of chats, the latter particularly in the coarser sizes. Such coarser middlings might be re-ground and returned to the classifier circuit, while the finer middlings went back to the same classifier to get another chance. If the loss in dressing the first concentrate and middlings up to shipping grade amounted to 11 lb. per ton, the final mill tailings would run 5 lb. per ton.

Present practice may perhaps be guessed at as producing a final tailing at 8·3 lb. per ton from 1% ore, composed as to two-thirds of sands at 5 lb. per ton, and as to one-third of slimes at 15 lb. per ton. A reduction to 5 lb. per ton on the whole tailing would mean an additional saving of 3·3 lb. per ton, equivalent to an increased recovery of 14·3% of the contents of the original feed, or an increase of 20% in the amount of saleable concentrate now produced.

At the prices which prevailed in April last, this would mean an additional annual income to the industry of £200,000.

I realize that this is an extremely bold claim to put forward as the result of a single series of laboratory experiments, and prefer to sub-

mit the figures which the experiments actually support without allowances for contingencies which can be supplied by the reader. It is apparent that it is quite possible to recover a high percentage of the slime-tin content of a pulp in a concentrated form if suitable means of dressing are provided. There is nothing disclosed showing that successful slime treatment is impossible through anything arising from the nature of slime tin itself, indeed the finest slimes panned gave the highest efficiences, and that there were two still finer products made by classification but not tested in this way does not imply that these would have to be run to waste, as Edser only rejected these as difficult to perform a second treatment on to establish a particular mathematical treatment, and states that they yielded a concentrate to framing.

Still greater improvements might be expected in the recoveries of arsenic and wolfram, as the present losses of these are mainly in the slimes.

It may be objected that a proposal to substitute buddling on a wholesale scale for the present semi-automatic handling of the pulp would lead to an increase in milling costs. A study of present slime plants will, however, show that many operations, although cheaply performed, are of such low efficiency that while each stage costs but little, the multitude of stages is responsible for a high total cost. The proposed system would have the effect of reducing the tonnage sent to the calciner and tin-yard, where the bulk of the manual handling takes place at present, and of rapidly reducing the tonnage handled at each stage.

Milling ore in which the tin is not exceptionally fine, and where a single-spigot is now employed in front of the stamps to feed tables of the Wilfley type, the overflow going to the slime plant, the battery pulp might be sent direct to the tables if these have sufficient capacity. These would be set to produce a sandy tailing for rejection going about 4 lb. per ton, after the slimes in it had been removed by a Bunker Hill screen or in some similar way. The oversize of this screen, which might amount to 30 or 40% of the whole mill-feed, would be rejected without further handling. A comparatively small table-concentrate would go direct to the calciner, and a large middling product would pass to a tube-mill running in circuit with a single-spigot classifier, the table-slimes joining the circuit at any convenient point. The whole product, suitably thickened, would pass to a multiple spigot hindered-settling classifier making eight or ten products, the spigot products going to separate buddles and the overflow to frames. It will be objected that there is no classifier now on the market designed to classify slimes in the manner required, classification not being practised at present below 200 mesh. It would not be possible to employ an existing type by modifying the velocity of the rising current, as the areas of the quicksand and sorting columns have to be relatively proportioned with regard to the size of the material with which they deal, and the problem would appear to be no more than one of design. The heads of the buddles would go to the calciner, the tailings to waste, while the middlings from the buddles treating the sandier products would be sent back to the tube-mill, returning via the multiple-spigot classifier, to which the middlings from the buddles treating the finer products would also be returned without further reduction. There would appear to be no good reason for calcining the different products apart, except perhaps as regards the original Wilfley product, and the whole calciner product would be passed through a similar multiple-spigot classifier and the products buddled. The heads would be tossed and buddled until fit for market, and the whole of the tails might require re-pulverizing, so that no part could be returned direct to the calciner-classifier for re-sorting.

In milling ores where the tin occurs in a fine state of division the probable procedure would be to pass the whole of the battery pulp, crushed through a fine grate, over Frue vanners without classification, pulling a high-grade concentrate for the calciner, and sending the whole of the tailings to the multiple-spigot classifier. The products sent to the buddles then being usually of lower grade than those handled in the previously considered case, a larger fraction of the buddle contents would be rejected as waste, and only a small proportion of the middles, if any, would be re-ground. Thereafter treatment would follow the lines already indicated.

CONCLUSIONS.—*Frames:* The sizes of particles saved on a smooth surface, as of a frame or vanner, are grouped about a definite mean magnitude and the tailings are characterized by intractability to re-treatment.

In the treatment of unclassified pulp, variations in dressing conditions within practicable limits do not greatly affect the technical result, except that a thicker pulp may possibly effect an increased saving of finer particles.

Washing is of value only as an expedient, and does not produce technical results otherwise unobtainable from the view-point of metal-

lurgical efficiency. Under appropriate circumstances, improved economic results may be obtained by its employment. The duration of the feed is the most important factor in deciding the technical result of a single operation on a frame. With a given ore, appropriate duration will vary directly as frame length, and there is no reason to anticipate better technical results on a short frame than on one of customary length. The customary duration of feed is too short to secure the best technical result of a single operation.

The technical result obtained by selection of the optimum length of feed period can also be secured by stage treatment in which the duration of feed in each stage is shorter. The combined tailings obtained by the latter method do not differ in character from those yielded by the other, and no better technical result finally is indicated apart from the simplification and cheapening of dressing which the other gives.

Classification of feed intended for treatment on frames or vanners is likely to produce inferior results. That better results can be obtained by classification coupled to the selection of appropriate dressing conditions remains to be established by research.

Buddles: Buddles should receive a classified feed. The close classification into a number of grades of the material now sent to the slimes plant, and its treatment by buddling, promises an improvement over present recoveries amounting to possibly 20%.

ON THE ESTIMATION OF MINERAL RESERVES.

With special reference to the Iron Ores of Cumberland and Lancashire.

By J. D. KENDALL.

ON pp. 45-48 of vol. viii. Iron Ores (Geological Survey) there are a number of statements on this subject so misleading and so utterly at variance with the recent practice of mining engineers that I am at a loss to understand why they have been allowed to appear in that publication.

Nineteen years ago, I invited the attention of the members of the Institution of Mining and Metallurgy to the very elastic use of the phrase "Ore in Sight." In many cases then it simply meant ore in imagination, which, I need hardly say, has not any marketable value, unless it be to the unscrupulous promoter. A long adjourned discussion followed the reading of the paper and, on my invitation, a committee was formed to consider the matter. As a result of the deliberations of that committee the

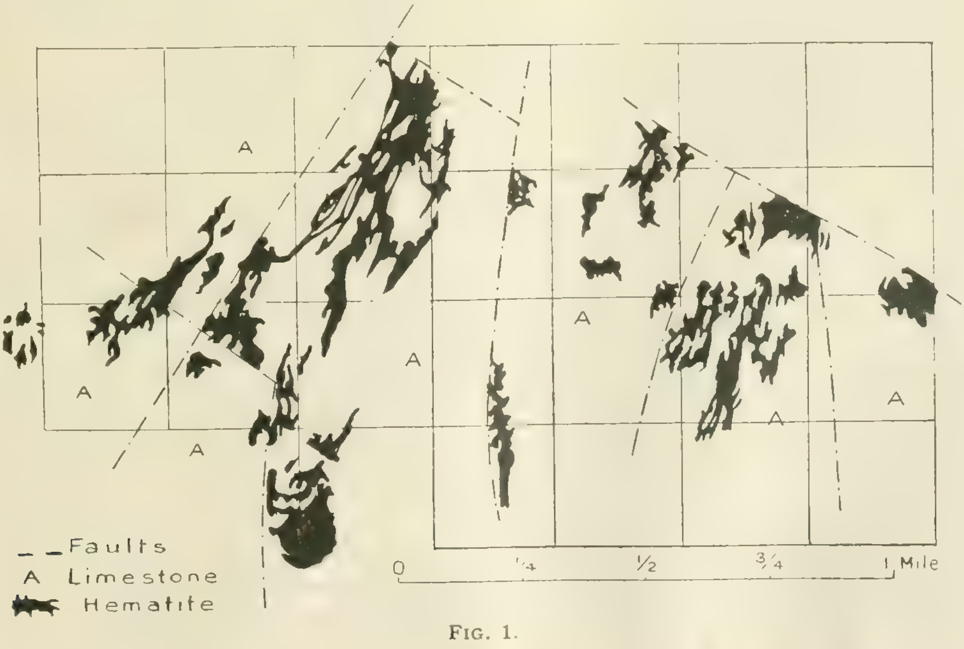

FIG. 1.

Institution sent out to its members a number of recommendations of which the three following are the essence:

(1) That members of the Institution should not make use of the term "Ore in Sight" in their reports without indicating, in the most explicit manner, the data upon which the estimate is based; and that it is most desirable that estimates should be illustrated by drawings.

(2) That as the term "Ore in Sight" is frequently used to indicate two separate factors in an estimate, namely: (*a*) ore blocked out, that is, ore exposed on at least three sides within reasonable distance of each other, and (*b*) ore which may be reasonably assumed to exist though not actually blocked out. These two factors should in all cases be kept distinct, as (*a*) is governed by fixed rules, while (*b*) is dependent upon individual judgment and local experience.

(3) That in making use of the term "Ore in Sight" an engineer should demonstrate that the ore so denominated is capable of being profitably extracted under the working conditions obtaining in the district.

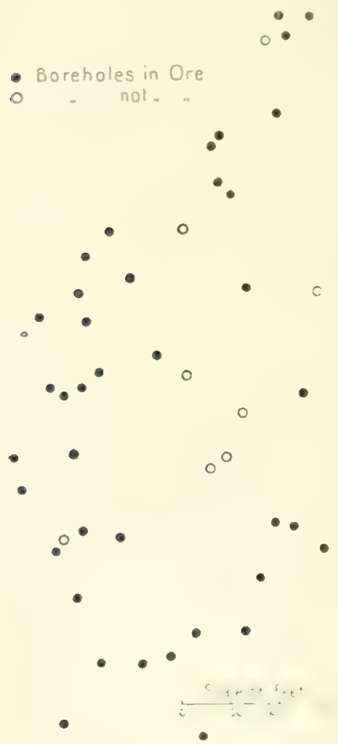

Fig. 2.

Since these recommendations were issued I have not seen anything so glaringly bad in the way of estimates as the passages from the Memoir above referred to, which I will now quote.

Referring to the possibility of finding further ore between Lamplugh and Egremont, the Memoir says on p. 45: "Assuming, in the absence of definite information, that ore is present in average quantity, we allow a reserve of 8 million to 10 million tons, some of which, however, may be difficult to win." In reference to the area south of Egremont we read on p. 47: "Provided that ore occurs as freely in this area as in the proved field to the north, there should be a reserve of about 50 million tons of ore, apart from that already allowed for in the Ullcoats-Winscales district." On the same page, a little lower, we read: "On the assumption that the ore occurs between the Hodbarrow Mines and the Park and Ronhead group as freely as in Furness generally, we estimate for this tract a reserve of some 24 million tons of ore, about equally divided between Cumberland and Lancashire." On p. 48 the following summary of reserves is given:

Fig. 3.

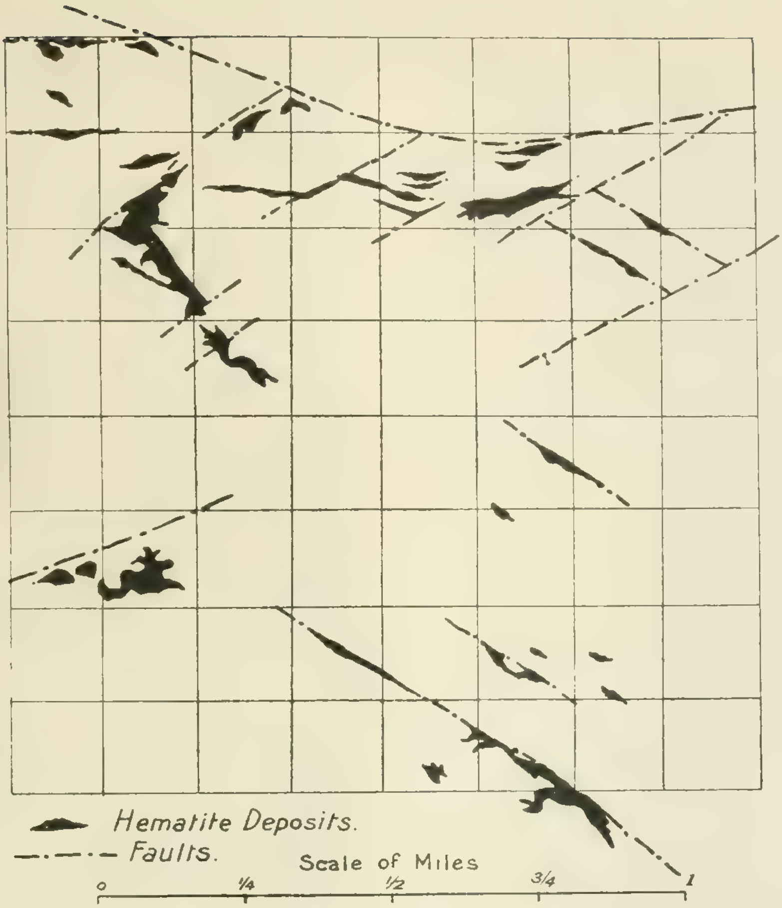

FIG 4.

		In Million Tons Proved	Unproved
Cumberland	Lamplugh-Egremont		10
	Egremont-Yotten Fews	40	50
	Millom District		12
Lancashire	West of Dalton		12
	East of Dalton	5	6
		45	90

The Memoir does not employ the phrase "Ore in Sight," but the word "Reserves." These are shown by the above table to be divided into two classes, "proved" and "unproved." Nothing is said as to how the proof, in the case of the former class, was effected, but in the sequel I will endeavour to show that it is impossible to estimate quantities in these ore-bodies with any approach to accuracy unless the ground has been blocked out.

Unproved reserves are reserves in anticipation and imagination only. That there is still a large quantity of ore to work beyond that blocked out in each of the three fields may be confidently expected. But how much no one can say, nor what proportion of it can be worked at a profit. The 90 millions of the Memoir is no more likely to be even the approximate total than 20 millions or 200 millions. There is as much justification for any one of these quantities as for either of the others. There is really no justification for fixing any quantity.

If 90 millions is not an aggregate of unadulterated guesses, it must have been reached by involving assumed quantities per unit area into unknown, because unexplored, areas. Such a product, it will be readily admitted, cannot be of the least value either commercially or scientifically.

Fig. 1 represents a part of the Whitehaven mining district, showing some of the most important deposits hitherto worked. They occur on different geological horizons, some in the First and Second Limestones, some in the Third and Fourth, others in the Seventh. It will be seen that there is no fixed relation between land areas and the areas of deposits in that land. Each of the squares in Fig. 1 has an area of about 41 acres. Some contain a

large proportion of ore, some very little. But that fact is still more evident when the area shown in Fig. 1 is looked at in conjunction with other parts of the district, where the spaces between the deposits are much larger.

Fig. 2 shows the positions of 49 bore-holes put down in a rich part of the district. Forty of these holes proved ore on the same geological horizon. Nine were in limestone. Twenty-five years ago I suppose most mining men who had not given serious thought to the vagaries of hematite deposits would have said that these holes—their positions and journals only being known—proved the existence of an ore-body interrupted by but a comparatively small extent of limestone. Let us see what was the fact.

Fig. 3 shows the plan of the ore-bodies, proved by the 49 bore-holes, after the deposits had been practically exhausted by the miner. It also gives the relative positions of all the bores shown on Fig. 2.

There were 4·44 times as many bores in ore as in limestone, but the area of the limestone, splitting up and enclosing the ore within the area covered by the holes, was 2·78 times larger than that of the hematite. To reconcile the results obtained in some of the bores with those of the miner it must be remembered that bore-holes are seldom if ever quite plumb and sometimes they are a long way from being so.

This is not a specially selected case to illustrate the erratic nature of these ore-bodies, as will be seen by reference to Fig. 1. There have been deposits in which the ore was less interfered with by limestone, but that could not be known until they were laid open, that is, until they were blocked out.

Fig. 4 is a plan of some of the more important deposits in Furness. It is on the same scale as Fig. 1, but many of the deposits shown on it have a vein-like habit, and therefore do not make so great a display horizontally as those in Fig. 1, nearly all of which have a bed-like form. Each square has an area of about 15·9 acres. All the deposits of importance that have been found in the area covered by Fig. 4 are shown on that drawing, but only a few of the larger faults. It will be seen that, as in the Whitehaven district, there is not any fixed ratio between the area of ore-bodies and that of the limestone in which they occur. Here, too, as at Whitehaven, it is impossible to estimate reserves that are not blocked out, and for the same reason.

If Fig. 4 be compared with Plate III. of the Survey Memoir, a fair idea may be obtained of the neglect of this district by the Geological Survey. Only two faults are shown on that plate in the area corresponding to Fig. 4, and neither of them exists in the ground, while the ore-bodies do not bear any resemblance to actuality.

A map of mere rock-areas is of very little value to the explorer. He wants to know the structure of the probable ore-bearing ground.

If it is not possible to form anything like an accurate estimate of the quantity of hematite that may exist in a deposit that has been pierced by 40 bore-holes, as shown by Figs. 2 and 3, what value can be placed on estimates in which—like those of the 90 millions of the Memoir—there is an entire absence of evidence?

LETTERS TO THE EDITOR

Genesis of Cumberland Iron Ores.

The Editor:

Sir—Mr. J. D. Kendall discusses the origin of the iron ores of Cumberland and Furness in a paper entitled "The bearing of the distribution of certain metallic minerals on their genesis," which appeared in the MAGAZINE for November, 1920.

He makes three points to which I desire to refer:

(*1*) Some of the veins of hematite occur in the Skiddaw slates, the Borrowdale rocks, the Ennerdale granophyre, and the Eskdale granite, in situations which he attempts to show were never overlain by Triassic rocks. The iron ore in these veins could not, therefore, he contends, be derived from the iron oxide of the Trias.

(*2*) The Permian breccia directly overlying a deposit of hematite in the Carboniferous Limestone near Orebank House, Bigrigg, in the Cleator district of Cumberland, contained angular fragments of hematite evidently derived from the deposit on which the breccia lay, and which deposit, therefore, must have been in existence before the breccia was formed.

(*3*) He contends that the view that the hematite deposits were formed by the downward filtration of iron ore from overlying Triassic rocks, "if held by those having the direction of explorations, would lead to a great waste of time and money."

As regards (*1*) I do not think we have sufficient data—we may never have—to decide how far the Triassic rocks extended over the Lake District. In the jumble of geological events so many things may have happened that it is safer not to dogmatize. As Mr. Kendall indicates, the late Mr. J. G. Goodchild thought that the Carboniferous and later rocks spread

at one time over the entire Lake District.

The northern part of the Isle of Man resembles in many of its features the Lake District. We have at the Point of Ayre the Saliferous Marls, then, going south, the Triassic and Permian, then the lower Carboniferous, and finally the Manx slate rocks rising to a height of 2,034 ft. at Snaefell.

Mr. Lamplugh, in his Geological Memoir of the Isle of Man, remarks on p. 1 : " The predominant feature of its stratigraphy is the central ridge of slate and greywacke, which seems to have constituted an insulated tract at as early a date as the beginning of the Carboniferous period. This prototype of the present island appears afterwards to have been enfolded and obliterated by the sediments of later times; but with the progress of denudation the old ridge has once more emerged from beneath this mantle." And on page 25 : " Before the commencement of the Carboniferous period, erosive influences had cut deeply into this old massif, the rocks of which at that time already possessed the lithological and structural characters that we find in them to-day. By this early denudation there seems to have been shaped out an isolated hilly tract approximately resembling the present land, which was probably afterwards buried under sediments of Carboniferous and later times, and thus during long ages protected from erosion. By the stripping away of these enfolding strata, probably finally accomplished during Tertiary times, the central position of the ridge was once more exposed, and must since have lost considerably in altitude."

Mr. Kendall's arguments in favour of a central tract in the Lake District that was never overlain by later rocks do not impress me. They seem to me to be mere speculations.

The certainties appear to be as follows: The Lake District is now more or less surrounded by belts of Carboniferous, Permian, and Triassic rocks. These beds formerly extended nearer the centre, covering a larger area of the Lake District than they cover now. The central mountains were pushed up. What area of the Lake District was once covered by Carboniferous and later rocks is speculative, and depends on another speculative matter, the dates of the various upheavals and sinkings of the mountains.

If I were to venture on a conjecture it would be something in this form. I would grant Mr. Kendall his island at the close of the Yoredale period, and this would account for " the occurrence of a rounded boulder of Ennerdale syenite (granophyre) in the shale between the Sixth and Seventh Limestones, at Crossfield mines." I would suppose the Lake District to be sinking and the Coal Measures to extend partly over it. With later sinking after the Coal Measures were laid down, rocks of Permian, Triassic, and possibly later date would be formed, creeping nearer and nearer the centre of the area and possibly entirely covering it. The Triassic rocks might then directly overlie " the Skiddaw slates, the Borrowdale rocks, the Ennerdale granophyre, the Eskdale granite," and furnish the iron contents of the hematite veins occurring in them. Then upheavals and denudation left the rocks as we now find them.

With respect to (*2*), if Mr. Kendall's account is correct it is a strong argument in favour of the genesis of the Cumberland hematite deposits before the formation of the Permian breccia. It is to be regretted that the particular evidence he describes is completely destroyed, and also that at the time it was available the fragments of hematite found in the breccia were not submitted to microscopical examination so as to attempt to determine if they were replacements of limestone fragments in the breccia by the same ferruginous solutions which Goodchild and others contend formed the irregular masses in the solid limestone below, and were not in fact fragments of hematite torn from a pre-existing deposit of hematite.

If the masses of hematite in the limestone were formed by descending ferruginous solutions, it would be surprising if these solutions on their way through the breccia did not attack and replace some of the limestone fragments in it. I am advised by geologists that an examination of such fragments might indicate whether they were replacements or fragments derived from a pre-existing mass. It is rather singular that such an examination has not been made, and I think the Geological Survey people have been remiss in not making the investigation.

I have endeavoured for some time to obtain specimens of hematite from the breccia so as to submit them for examination, but so far I have not been successful. It is not necessary that the specimens should come from breccia directly overlying a deposit of hematite. If it was found that the pebbles and fragments of hematite in the breccia were replacements of limestone fragments *in situ*, it would weaken Mr. Kendall's views as to the date of the deposits in the body of the limestones. It would not, however, prove the downward filtration theory, as it could still be urged that ascending

solutions or vapours had affected both limestone and overlying breccia.

Great light would be thrown both upon the genesis and the age of hematite deposits by a microscopical examination of the pebbles and fragments of hematite found in the Permian breccia, and to this matter I would strongly direct the attention of geologists.

The proximity of Triassic rocks to the Carboniferous Limestone cannot be urged as a reason for not expecting hematite as (*3*) would seem to imply. Even if, as Mr. Kendall thinks, the iron oxide from the Trias played no part in the formation of hematite deposits in the underlying limestone, yet he cannot deny that, in the hematite districts of Cumberland and Furness as well as in North and South Wales, the Forest of Dean, and Derbyshire, Triassic rocks are in close proximity and can with some certainty be said to have overlain at one time the areas where the deposits occur. Indeed, in the southern part of the Cleator district of Cumberland, and in parts of the hematite district of South Wales, hematite is or has been worked in the limestone now overlain by Trias.

I fail, therefore, to see how it can be argued that even if the Trias has no relation to hematite deposits in the limestone any loss of time or money in exploration can result from the opposite view.

J. B. ATKINSON.

86, St. George's Terrace,
Newcastle-on-Tyne, December 14.

The Editor:

Sir—In the last paragraph of Mr. J. D. Kendall's interesting article in THE MINING MAGAZINE of November last, he alludes to the chemistry relative to the deposition of the North-West of England hematite deposits. It is a well-known fact that gypsum is comparatively abundant in the Triassic strata. Is it not reasonable to infer that the gypsum is very likely the residual salt resulting from the replacement of the Carboniferous Limestone by hematite through the agency of powerful solutions of ferric sulphate from below? That reaction is conveniently represented by the following equation:

$$3CaCO_3 + Fe_2(SO_4)_3 = 3CaSO_4 + Fe_2O_3 + 3CO_2.$$

If this reaction can be taken as probable, then we have still further evidence of mineralization from below. Whereas, on the contrary, no striking abundance of gypsum is found below the Carboniferous Limestone. It would be interesting to know whether, in the opinion of Mr. Kendall, the amount of gypsum in the Triassic strata could represent a residuum from the reaction that I suggest.

A. ALEC JONES, Assoc.Inst.M.M.

Millom, Cumberland, January 8.

The Editor:

Sir—I thank you for letting me see Mr. Jones's and Mr. Atkinson's letters so that my replies may appear in the same issue.

In his letter, Mr. J. B. Atkinson has, I assume inadvertently, omitted the evidence on which he bases the numerous statements made. If he will be good enough to supply this most important deficit his readers will, I think, be able to form a more reliable judgment. If, for instance, we take paragraph 11, in which Mr. Atkinson first puts forth his ideas, we find the following statements: "If I were to venture on a conjecture it would be something in this form . . . : I would suppose the Lake District to be sinking and the Coal Measures to extend partly over it. With later sinking after the Coal Measures were laid down, rocks of Permian, Triassic, and possibly later date would be formed, creeping nearer and nearer the centre of the area and possibly entirely covering it. The Triassic rocks might then directly overlie the Skiddaw Slates, etc." Here we have a number of suppositions but no evidence.

The next paragraph seems to indicate that Mr. Atkinson is not sure of my presentation of the facts relating to the occurrence of ore fragments in the Breccia near Orebank House. But he does not say why. I invite him to do so. As I have previously told Mr. Atkinson, I sliced hematite fragments from the Breccia, for microscopic examination, 40 years ago, but found no difference between them and pieces taken from the mine. In both, the sections varied considerably, some containing numerous minute quartz-filled cavities. In others there was nothing but iron ore. Mr. Atkinson says, "Great light would be thrown both upon the genesis and age of hematite deposits by a microscopical examination of the pebbles and fragments of hematite found in the Permian Breccia." One would naturally expect, after, or before, a positive statement like this, some evidence would be adduced, for Mr. Atkinson says *would*, not *might*.

To the last paragraph of the letter I need not add to what I have said elsewhere, beyond this: "Hematite is or has been worked in the limestone now overlain by" boulder clay (Mr. Atkinson says Trias), but that is not any reason for thinking there is some intimate relation between them. It is merely an incident in geological evolution. The same statement may

be made with reference to the Trias.

In reply to Mr. Jones's letter, there are two reasons why the suggested reaction cannot, in my opinion, be accepted as an explanation of the facts. (1) The volume of calcium carbonate required as precipitant is so much in excess of the volume of hematite precipitated that the cavities formed in the limestone would be very much larger than the ore-body. (2) The ore and the gypsum referred to were not formed at or near the same time.

J. D. KENDALL.

London, January 28.

The Finsbury Technical College.

The Editor:

Sir—In an article published under the above heading in THE MINING MAGAZINE for November, reference was made to the threatened extinction of the Finsbury Technical College, and a powerful appeal was put forward for the continuance of this historic school of engineering and industrial chemistry. One emendation may, however, with advantage be made in this otherwise excellent notice, in regard to two references to the Board of Education as the authority which contemplates closing the College. On the contrary, although the Board has never had official relations with the College, yet it has on at least two recent occasions expressed warm sympathy with the movement set on foot by the Finsbury Technical College Defence Committee. Hitherto the Board of Education has not been called upon to contribute towards the financial support of the College, this responsibility having been undertaken solely by the City & Guilds of London Institute for the Advancement of Technical Education. The Board has, however, intimated that if the future of the College could be assured it would be prepared to offer material assistance.

In a statement issued by the City & Guilds of London Institute last July a survey is made of the circumstances in which the Institute is constrained to terminate the educational work of the College in July, 1921. With much of this explanatory statement those interested in the scientific and technical education of the Metropolis will have the fullest sympathy. It is evident that the Institute is averse from entering into competition, on very unequal terms, with institutions liberally subsidized by the Local Education Authority, which in the present instance is the London County Council. The Defence Committee has, however, found strong support for the view that there is still abundant scope for the continued existence of the pioneer technical college of the London area. The great traditions of instruction and research associated with the memory of such illustrious teachers as Ayrton, Perry, Meldola, and Silvanus Thompson, and the undiminished success of the College under their successors, constitute a priceless asset worthy to be conserved and utilized in the training of future generations of students of applied science. With the spread of the Finsbury Defence Movement it is becoming more widely realized that it is precisely this side of the Institute's activities for which there is at present the greatest need. In regard to the recent past, the imperial importance of the Institute's work in the College may be gauged by the war services rendered by the staff and former students of Finsbury. "Happy is the man that hath his quiver full of them, for he shall not be ashamed when they speak with the enemy in the gate."

G. T. MORGAN.

London, December 29.

NEWS LETTERS.

MELBOURNE.

December 9.

WELFARE SCHEMES AT MOUNT LYELL.—During the past three or four years the Mount Lyell company, like many other big industrial concerns in the Commonwealth, has been carrying out a welfare scheme for its mining employees, the bulk of whom reside at Gormanston, near the mines, the principal feature being the provision of comfortable and adequate housing accommodation. This problem, in an isolated district like Mount Lyell, is naturally a difficult and expensive one to overcome, but the company is striving earnestly and determinedly to cope with it, and the results are highly gratifying. There has just been finished a block of ten houses, which makes a total of 38 erected since the initiation of the scheme. The dwellings contain four or five living rooms, and are built of hardwood, lined throughout with either similar wood or 3-ply material. They are of simple and neat design, and have been built under the supervision of Mr. R. M. Murray, engineer-in-charge of the mines, and his staff. Malthoid and shingles are used for roofing, and, in addition to the four or five living rooms, each dwelling is furnished with pantry, scullery, washhouse (in some instances a bathroom), woodshed, and sanitary accommodation. The land is sufficient to provide reasonable yard and garden space, which is all securely fenced. Electric lighting, heating, and power are sup-

plied direct by the company at the reasonable rate of 4d. per unit for lighting and 2d. for power, and the water supply is provided by the municipal council. The building of these houses is, however, not by any means the limit of the company's efforts in this direction, as, in addition to the 38 houses built, they have purchased from time to time other dwellings, many of which were in a dilapidated state, and made them fit to live in. Altogether the company owns in Gormanston about 100 houses for the benefit of their mine employees. The rent charged for the dwellings is only 7s. 6d. per week for a four-roomed and 9s. for a five-roomed cottage, and it is fairly safe to say that in no industrial centre or large city of the Commonwealth can as good houses be found for ordinary workers of all classes as those which the Mount Lyell company is providing for its mine employees at such low rentals.

Another detail of the scheme is the promotion of direct trading, by what are virtually co-operative establishments. The company, for about 18 months past, has been the only supplier of meat in the Gormanston centre, having purchased the businesses of those local butchers who complained that they could not carry on owing to the high price of stock. Under the company's management the meat supply business has been reorganized on lines which mean a reduction of 2d. and 3d. a pound as compared with the prices charged by private firms. In furtherance of their scheme, the company, a few months ago, also acquired the principal general stores in the municipality, and are now supplying groceries and general food commodities, household ironware, crockery, etc., and in the clothing line all classes of working requirements, including blueys, oilers, and boots. With a view to encouraging the cash system of trading, and eliminating, as far as possible, the credit system, the company offers every inducement to the people to pay cash and thus get their goods at the lowest possible prices. All purchasers of meat who pay cash at the shop are allowed 1d. per lb. as against that sold on the fortnightly credit basis, while at the general store the buyer paying cash is allowed 10% discount, and there is no doubt that a very large number of the consumers are taking advantage of the benefits of this cash system.

Another item in the welfare scheme is the providing of facilities for improving social life, and to this end the company has established and equipped recreation halls at both Gormanston and Linda, where for 6d. a week comfortably furnished billiard, reading, and pastime rooms are available to the employees and the public generally, and this in itself is a great help towards minimizing the unfavourable climatic and living conditions which are inseparable from a rough and isolated district like the Mount Lyell mining field.

It must be understood that, although the company is financing the business and taking the responsibility of monetary loss, it is not out to make any profit whatever in its trading department. The business is purely co-operative, with practically no expense or risk to the employees (and employees in this connection means the whole of the Gormanston community, every member of which, if not directly, is certainly indirectly, employed by the company), the principle aimed at being the supply of goods at cost price, after allowing for the cost of purchase, management, and distribution, thereby eliminating the retailer's profits. As the turnover in the butchering and general store business is approximately £60,000 a year, it will easily be realized what an appreciable benefit this trading department is to the employees and the public of Gormanston generally. The men as a body are not at all backward in acknowledging the efforts of the company to establish sympathetic relations with their employees. If the result of the Mount Lyell Co.'s action in this direction is to eliminate strikes or other industrial troubles, and prevent stoppages of work, the money will have been well spent.

ELECTROLYTIC ZINC IN TASMANIA.—The works near Hobart of the Electrolytic Zinc Co. of Australasia, which were started in 1917, now employ some 1,200 workmen, and rapid constructional work is being carried on. A representative of the *Industrial Australian and Mining Standard* has made a tour of inspection in company with the general manager, Mr. H. W. Gepp. In addition to the buildings, wharves are being constructed along the banks of the Derwent 1,000 ft. in length and 60 ft. wide, with a depth of 30 ft. at low water, in readiness for the shipments which will be necessary to deal with the 100 ton per day output. Mr. Gepp states that the company will be exporting annually 10,000 tons of zinc oxide, 15,000 tons of zinc-lead oxide, and from 10,000 to 15,000 tons of lithophone, with quantities of rolled zinc sheets and silver and lead in bullion, in addition to the daily output of 100 tons of zinc. At present 25 tons of zinc are being produced in addition to by-products, and it is anticipated that by next November the output will be 50 or 60 tons per day. [Owing to the low price of zinc, production has been suspended

since this letter was written, but the construction of new plant and buildings is still actively in hand.—EDITOR.] At present only 5,700 h.p. is delivered by the State Hydro-Electric Department, but when the full 30,000 h.p. contracted for is supplied and the 100-ton plant is in full operation, some 100,000 tons of concentrates will be imported yearly from Port Pirie and some 35,000 to 40,000 tons of zinc and about the same quantity of other products will be exported from Hobart, so it is evident that some shipping accommodation will be required. A power house is being built of reinforced concrete to contain seven rotary converters, and the full 30,000 h.p. will come here direct, and when the machinery on order from Rugby is installed the building will contain £150,000 worth of electrical equipment. This building will be 200 ft. long and 60 ft. wide, the walls being 40 ft. high. Six of the seven converters will be in constant use. Overhead cranes will be installed for the purpose of lifting out the machines for overhaul or repair in the adjacent workshop. A conveyor is being built which will take the concentrates on an endless 30 in. belt from the steamers to the bin, which will hold about 20,000 tons of concentrates. Distributing conveyors are also to be erected from the bins to the final roasters, and from there to the leaching plant, etc. Electric shovels are to be installed at the bin for lifting the concentrates on to the conveyors. A carpenter's shop is also being specially designed for the making of the 50 ft. vats used for the supply of solutions to the cell-room. The butcher's shop, now nearing completion, is replete with every modern convenience, and is fitted with a refrigerator chamber. This shop is being run in conjunction with the company's co-operative stores and under the direction of the employees' co-operative council, which deals with all matters relating to the health and recreation of the workers. The latest venture is the importation of machinery for the making of barrels of ply-wood. The ply will be cut from green myrtle timber, and the barrels will be used for exporting the by-products. The company has its own saw-mill and a large seasoning yard on the property.

A model village is being built on the slope of the hill near Prince of Wales Bay, and this has been laid out on the best garden-suburb lines, there being a perfect panorama of river, mountain, and orchards, with not the least suggestion of the deadly monotony of suburbia. A dozen different styles of houses have been built of concrete, in chalet and bungalow style, roofed with concrete tiles, corrugated iron, and shingles, and the tenants can take their choice. As the site was previously an orchard, the fruit is ready to be picked as the tenants take possession. Some 23 houses are already occupied, and as many more are nearing completion. Sixty are to be built on the orchard site, and another 120 are to follow on a site above the main road.

TORONTO.

January 12.

COBALT.—The production of silver has been greatly curtailed by the shortage of electric power. Only some 10 mines out of 19 that were being operated during the summer are now working, and it is doubtful as to whether they will be able to continue in operation until spring. But for the unusually mild weather which has so far prevailed, conditions would have been still more serious. Working forces have been considerably reduced at those mines which are still producing, and only about 1,000 men are now at work as compared with some 2,000 last summer. The wage scale, which has been maintained so far at the same rate which prevailed when the price of silver was high, will be reduced by 75c. per day or approximately 15% from February 15. Among the mines which have recently closed down are the Beaver and the McKinley-Darragh, both of which are being kept clear of water in readiness for the resumption of work as soon as power is available. The Nipissing is the only mine which has not reduced its output. During December it produced silver of an estimated net value of $299.894. Its production of cobalt metal during 1920 was valued at $224,204. At the Bailey a 2 in. vein of high-grade ore, running 4,000 oz. to the ton, recently discovered on the 240 ft. level, is being developed. During November the company made gross earnings of $13,668 from the treatment of 4,556 tons of ore. Three high-grade veins discovered on the surface of the Kerr Lake have proved disappointing under development, as the enrichment apparently extends only a few feet downward. A new company, entitled the Ruby Co-operative Silver Mines, Ltd., with a capitalization of $1,500,000, has been formed to operate the Ruby mine in Bucke township. High-grade ore has been encountered on the 100 ft. level. The annual report of the Coniagas showed an output of 994,235 oz. of silver from the treatment of 97,624 tons of ore, as compared with 940,267 oz. during the previous year. The mine is now solely dependent upon the concentration of ores averaging about 10 oz. to the ton, and the re-treating of accumulations of sands and slimes which yield a moderate profit. There has been

a total distribution to shareholders as dividends and bonuses of $10,140,000.

PORCUPINE.—The available supply of electric power for the mines, which is considered as assured for the winter, is only about 4,000 h.p., an amount far below normal requirements. This is being allotted to the mines which have contracts with the power company. The Hollinger Consolidated receives about 2,000 h.p. which, together with about 1,400 h.p. generated by its auxiliary steam plant, enables it to maintain a fair rate of production. The Dome mines with 1,000 h.p. is working at considerably reduced capacity, treating an average of about 500 tons daily. It is not expected that the decrease in output will interfere with the payment of the regular dividends, as activity will be resumed on a larger scale than ever in the spring. The McIntyre receives only a small allowance of power, but its auxiliary equipment enables the company to continue operations at about two-thirds capacity. The North Crown, which receives 250 h.p., is carrying on cross-cutting at the 500 ft. level, where two veins, one 5 ft. and the other 10 ft. in width, have been encountered. Negotiations are in progress with a view to an amalgamation of the North Crown and the Vipond-North Thompson, which would give the new company a combined area of 320 acres and enable important economies in working the properties to be carried out. The annual report of the Porcupine-Keora states that diamond-drilling shows that the gold content of about $6 per ton found in outcropping veins continues at a depth of 1,000 ft. The Clifton-Porcupine has suspended operations on account of the difficulties in the way of raising funds by selling treasury stock under present conditions.

KIRKLAND LAKE.—There has been a considerable influx of labour into this camp from Cobalt, and mining staffs have been increased. The Lake Shore, during November, treated 1,810 tons of ore with a recovery of $49,339, being an average of $27·25 per ton. The shaft is down to the 600 ft. level and sinking has been temporarily stopped until a cross-cut has been run at that depth to tap two veins. The Ontario-Kirkland is developing ore on the 300 ft. and 450 ft. levels, which assays from $8 to $28 per ton, and has enough in sight to supply the mill for two years. Machinery and supplies will be brought in during the winter and the construction of the mill will be pushed in the spring. The Kirkland Lake has made a shipment of gold bullion produced during December of the approximate value of $30,000. The King Kirkland has ordered a mining plant, and following its installation will begin the development of promising surface outcrops. Plans for a merger of the Teck-Hughes and Orr mines are being considered, involving the formation of a new company capitalized at $5,000,000 in shares of par value of $1. The Teck-Hughes interests, including the bondholders, will receive 2,500,000 shares, the Orr stockholders to get 1,500,000 shares, leaving the remainder in the treasury.

LARDER LAKE.—The Associated Goldfields has been reorganized under a new charter as the Canadian Associated Goldfields, Ltd., capitalized at $30,000,000, each stockholder receiving four shares of the new company for each share in the Associated Goldfields. George A. Gray, who was for several years chief engineer at the Dome Mines, Porcupine, has been appointed general manager.

MINERAL PRODUCTION OF 1920.—A preliminary estimate of the mineral production of Canada issued by the Department of Mines gives the total value as approximately $200,000,000 as compared with $176,686,390 in 1919. The principal increases are: copper from 75,053,581 lb. to 82,500,000 lb., zinc from 32,194,707 lb. to 42,000,000 lb., nickel from 44,544,883 lb. to 61,500,000 lb., and coal from 13,681,218 tons to 16,000,000 tons. The output of gold is estimated at $16,000,000, being a slight increase, and silver shows a decline from 16,020,657 oz. to 13,500,000 oz.

CAMBORNE.

THE TIN MINES.—The up and downs of Cornish mining are proverbial, but never, in the known history of the industry, has such a bad period as the present been experienced. The only mine, of any size at any rate, in full swing is East Pool & Agar, and here the monthly loss is such that unless there is a speedy recovery in the tin and arsenic markets, operations even at this famous mine will have to be brought to a standstill. [Since the above was written, notice has been issued for a stoppage of mining.—EDITOR.] Indeed, but for the financial foresight of the board in getting together a substantial reserve fund when handsome profits were being earned, it is clear that the company would not have been in a position to continue the struggle so long, and like many of the other concerns, weakened by the effects of the war, would ere this have been shut down, probably never to be reopened. South Crofty has suspended operations, but the mine is being kept unwatered and a little development done. Fortunately the pumping charges here

are light, so there is hope that absolute closure may be avoided, so long as East Pool continues in fork. At the latter mine, the incoming water is exceedingly heavy, particularly during the winter months, so that even if active mining operations were suspended, and only pumping continued, the monthly loss would still probably be over £5,000. The staff and employees at East Pool have agreed to a reduction in wages which will help matters a little, and we commend the good sense of the men and their leaders in their attitude in this matter. In the St. Just district, doubtless under the advice of the Union leaders (incidentally a different Union), the men have declined to accept any reduction, with the result that operations at Levant and Geevor have been suspended and the men are being forced to subsist on the unemployment donation. Under the circumstances, probably these companies are the gainers, but it is difficult to understand the attitude of the men, particularly when one remembers that they have always been most considerately treated by Mr. Oliver Wethered and his colleagues and that the rates of pay in the St. Just district were higher than elsewhere. At Tresavean and Porkellis, only the pumps will be kept working. With tin metal at £165 per ton, even alluvial undertakings cannot be operated at a profit with present working costs, so that there must surely be a recovery in price within the next few months. We hope it may be soon, for if not, the dirge of Cornish tin-mining will have to be sung. With coal at its present exorbitant price, and we note with dismay that a further increase is threatened, even pumping operations only cannot long be continued. No further move has been made to secure new capital for Dolcoath under the scheme outlined in the last issue, and this postponement is wise, for even local people would not have had the courage to put up more money under existing conditions. The difficulty will be to find the money to enable the water to be kept below the level of the proposed Roskear exploratory cross-cut, but we hope this may be done.

CHINA CLAY.—Tehidy Minerals, Ltd., has recently purchased the Halviggan china-clay works owned by Messrs. Pochin & Co., situated near St. Austell. The output of these pits is stated to be about 20,000 tons per annum. The terms of the purchase are not stated. Presumably, the company's own china-clay properties in this district will be worked in conjunction with Halviggan.

A new company is now to be formed to re purchase from Mr. Mallaby-Deeley the works of the China Clay Corporation on Dartmoor for the sum of £47,000. This is the actual price Mr. Deeley paid for the property at the recent sale. The new company will be capitalized at £75,000, so that £28,000 will be available as working capital, which is believed to be adequate, bearing in mind that close on £200,000 was spent by the previous owners on equipment and development.

Australia's Metal Output, 1920.

The Imperial Mineral Resources Bureau has received from its Corresponding Member in Australia cable information, from which the following table is prepared, relative to the mineral industry of the Commonwealth of Australia for the year 1920.

	Production. Tons.	Exports. Tons.	Imports Tons.	Home Consumption Tons.
Copper—				
(a) bar copper ...	23,069	28,612	—	5,231
(b) in blister copper	2,000	2,000	—	—
(c) in copper ore ...	115*	115	—	—
Lead –				
(a) lead	4,077	50,069	—	13,992
(b) in lead bullion ...	1,939	1,798	—	—
(c) in concentrates	4,122*	4,122	—	—
Zinc	9,665	5,689	—	6,456

PERSONAL.

DR. FRANK DAWSON ADAMS has been appointed vice-principal of McGill University.

GEORGE RENNIE AIRTH has returned from Trinidad.

DR. J. MACKINTOSH BELL is here from Canada.

J. E. BREAKELL has returned to West Africa.

J. M. CAIRNS is back from Spain.

WILLIAM CALDER has left for Trinidad.

G. W. CAMPION has left London on his return to West Africa.

SIR W DALRYMPLE is here from South Africa.

CLEMENT DIXON has arrived from Rhodesia.

SIR GEORGE DOOLETTE, chairman of Great Boulder Proprietary, celebrated his 81st birthday on January 24.

C. H. FELDTMANN has been appointed metallurgist to the Colombian Mining & Exploration Co., and left on February 14.

DONALD GILL has left for France.

THOMAS GIRTIN has joined the board of Johnson, Matthey & Co., Ltd.

F. H. GRANSTEDT has been appointed manager of the Leviathan tin mine, New South Wales.

DR. EUGENE HAANEL is resigning the directorship of the Mines Branch of the Canadian Government under the age-limit regulation.

A. F. HASELTINE has been appointed principal of the Ballarat School of Mines.

(Continued on next page.)

LOFTUS HILLS, Government Geologist for Tasmania, is making an examination of the Mount Lyell region.

WILLIAM HOSKING, who was for twenty years mineral agent for the Tehidy Estate, when under the ownership of Mr. Basset, has opened an office as consulting mining engineer, at 18, Penventon Terrace, Redruth.

BERTRAM HUNT has joined the London staff of the Dorr Company as chemist and metallurgist.

P. F. KENDALL will be resigning the professorship of geology in Leeds University next June, under the age-limit. Professor Kendall is well known for his work in connection with the concealed coalfields of Yorkshire and the Midlands.

MARK R. LAMB, of New York, is visiting South America.

GEORGE C. MACKENZIE has been appointed secretary of the Canadian Institute of Mining and Metallurgy.

C. H. MACNUTT has resigned as manager of the Black Lake Asbestos & Chrome Co., Ltd., and is now in charge of the Vimy Ridge property of the Bennett-Martin Asbestos & Chrome Mines, Ltd., at Coleraine, Quebec.

ERIC NEWBOLD has gone to New Mexico.

DAVID PENMAN has been appointed principal and professor of mining in the new School of Mining and Geology to be founded at Dhanbad in the Bihar-Orissa coal-mining district, India.

C. W. PURINGTON is back from Okhotsk, far east Siberia.

H. K. SCOTT has returned from the Gold Coast.

J. E. SPURR, editor of the *Engineering and Mining Journal*, has been elected president of the Mining and Metallurgical Society of America.

W. C. STEPHENS, managing director of the Climax Rock Drill & Engineering Works, Ltd., is on his way home from the Rand.

G. W. EATON TURNER has returned from Colombia.

DR. ARTHUR WADE has returned from Australia, and is now acting as consulting engineer to the Commonwealth with office at 91, Basinghall Street, E C.

WILLIAM WHYTE, lately underground manager at the Messina mine, has gone to Colombia for the Colombian Mining & Exploration Company

OWEN B. WILLIAMS has been appointed manager of the North Mount Farrell mine, Tasmania.

JOHN BARRY, chairman of the California Exploration Co. and the Plymouth Consolidated Gold Mines, and a director of the Sons of Gwalia, died on January 27.

SIR LAZARUS FLETCHER, for so many years keeper of the mineral collection at the Natural History Museum, at South Kensington, and later Director of the Museum from 1909 to 1919, died last month.

DR. REGIS CHAUVENET, emeritus professor of chemistry at the Colorado School of Mines, Golden, Colorado, died on December 5, in his 78th year. Dr. Chauvenet was born in Philadelphia, on October 7, 1842. He graduated from Washington University in 1862 with the degree of Bachelor of Arts, and in 1864 he received the degree of Master of Arts. In 1867 he received the degree of Bachelor of Science at Harvard. In 1900 his alma mater conferred upon him the degree of Doctor of Laws. From 1871 to 1883 Dr. Chauvenet had an office in St. Louis as an analytical chemist, and was not only successful in a financial way, but won a wide reputation technically. During this time he was chemist to the Missouri Geological Survey. From 1872 to 1875 he was also city gas inspector for St. Louis. In 1883 he was called to the Colorado School of Mines as president and professor of chemistry and metallurgy. It was largely through his high educational ideals and efforts that the School won its place among the institutions of higher learning of the world. In 1902, after a service of twenty years, he resigned and again entered private practice as a consulting engineer and chemist, with offices in Denver. Though resigning as active head of the School, for many years he was a special lecturer in the chemistry and metallurgy departments. During the latter years of his life he devoted most of his time to writing a history of the School. In 1911 he issued a volume on "Chemical and Metallurgical Calculations" which enjoyed a wide circulation.

TRADE PARAGRAPHS

HENRY BATH & SON, LTD., of 53, New Broad Street, London, E.C.2, Swansea, and Liverpool, send us their chart giving the average monthly cash prices of copper, tin, lead, and spelter.

A. GALLENKAMP & CO., LTD., of 19 & 21, Sun Street, Finsbury Square, London, E.C.2, send us their catalogues of filter papers and porcelain and glass ware for laboratory purposes

N. TAYLOR & SONS, of 17, Goree Piazzas, Liverpool, send us their pamphlet relating to hydro-carbonated bone-black for case-hardening, which gives a description of the process.

SANDYCROFT, LTD., of Chester, and 4, Broad Street Place, London, E.C.2, have acquired from Chalmers & Williams, Chicago, the sole licence for manufacturing the Symons Disc Crusher in England.

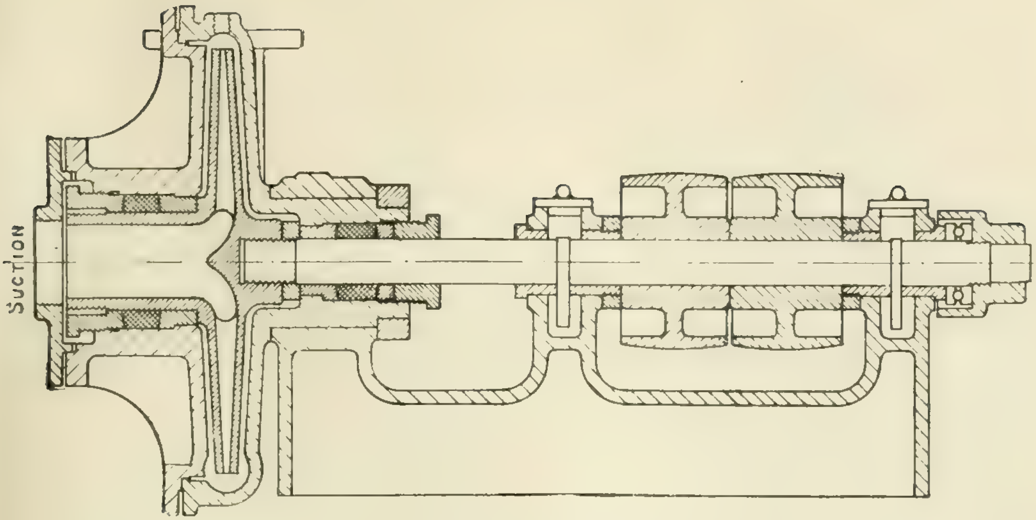
THE CONSOLIDATED PNEUMATIC TOOL CO., LTD., of 170, Piccadilly, London, W.1, have appointed J. A. Angus, of Kaims Foundry, Strand Road, Rangoon, their agent for Burma.

THE EDGAR ALLEN NEWS for January-February contains a number of interesting articles. One is by C. K. Everitt describing special steel processes; a second gives information relating to instruments for measuring temperatures in heat treatment of steel; a third is devoted to the application of the Stag ball-mill to the production of fine stone-dust used in dusting the roads of collieries.

THE BRITISH ROPEWAY ENGINEERING CO., LTD., of 34, Fenchurch Street, London, E.C.3 (purchasers from the Government Controller of Bleichert's Aerial Transporters, Ltd.), send us a pamphlet describing the application of their ropeway to the automatic disposal of refuse of all descriptions. In mining it is applicable for the dumping of tailings and waste rock, refuse from coal washers, etc.

THE INTERNATIONAL BARGE SUPPLY & TRANSPORT CO., LTD., of 5, Lloyds' Avenue, London, E C.3, send us a pamphlet describing their barges, which are built of steel, and are suited for propulsion by petrol engines or for towing purposes. Each barge is divided longitudinally into four sections, so that a number of them can be packed in one big motor-driven barge for transport to their destination abroad. The sections can be easily put together on arrival.

THE STURTEVANT ENGINEERING CO., LTD., of 147, Queen Victoria Street, London, E.C.4, send us a book describing their installations of machinery for making superphosphate manures. The preparing plant described includes vertical rotary crushers, ring-roll mills, Newaygo screens, air separators, dust collectors, etc., and jaw crushers and rolls for breaking iron pyrites. The book also describes the plant for producing superphosphate by acting on the phosphate with sulphuric acid.



THE WILFLEY CENTRIFUGAL PUMP.

THE WILFLEY CO., LTD., of Salisbury House, London, E.C.2, send us particulars of a new type of centrifugal pump which they are putting on the market. The pump differs from that of the ordinary type in that the impeller is fitted with a hollow trunnion through which the suction water passes on its way to the impeller passages, and the trunnion itself runs in a packed gland, with the result that leakage of water from the delivery to the suction side is prevented, a source of loss liable to occur in centrifugal pumps of ordinary design. Owing to the water entering on one side only of the impeller there is an end thrust which is taken by a ball thrust-bearing on the driving shaft. The main dimensions of the pump are: Diameter of impeller, 12 in.; diameter of interior of trunnion, 1·75 in.; angle of blades, 20°; diameter of suction pipe, 2½ in.; diameter of delivery pipe, 2 in. Tests made by Professor John Goodman, of Leeds, showed that the pump lifted a maximum of 111½ gallons to 125 ft. at a low speed of 1,500 r.p.m., and 193 gallons to 53 ft. at a speed of 1,320 r.p.m. A suction lift of 33 ft. water was obtained at 1,590 r.p.m. with the barometer standing at 35·5 ft. It is believed that no centrifugal pump has lifted previously more than about 20 ft. suction, and the usual total lift in one stage does not exceed about 80 ft. The efficiencies obtained were, it is believed, greater than could be obtained with so small a pump of the ordinary type, while such high lifts could only be reached by multi-stage pumps of high-grade construction. The pump tested by Professor Goodman is quite rough, and there is no internal machining of the case or the impeller, excepting that the trunnion of the impeller, which is the novel feature, is of course turned to fit the stuffing box glands.

METAL MARKETS

COPPER.—Prices of this metal declined further during the month of January, this remark applying to both standard and electrolytic copper in this country. So far as the price of electrolytic is concerned, the fall is, of course, largely on account of the improvement in the rate of dollar exchange, as, so far as the American market is concerned, things have not on balance become any easier during the period in question. Indeed at one time some firmness was in evidence there, and there seemed to be a little more doing, but latterly this apparent spasm of strength evaporated. Generally speaking the whole copper situation has not very materially altered. The stocks on hand in America are still big. The exact quantity is not known, and various estimates are put forward, one being that there is about 390 000 tons of copper in existence there, this of course doubtless including blister copper as well as the refined product. In the meanwhile consumption everywhere remains on a very restricted scale. It is difficult to form an estimate as to the future of the market. On this side the price depends to a large extent on whether the recent improvement in the dollar exchange is maintained. There is a general movement in America to curtail production, but of course it must be a little time before this becomes evident. This, however, should help the market in the long run. For example, the Calumet and Arizona, it is stated, has now reduced output to between 35 and 40% of capacity. Until the last two or three months of 1920 curtailment did not materially affect the company's cost, the production figure averaging about 13½ cents. Under the new basis it is expected that the cost will show some expansion. Curtailment is also evident in the December production figures of the four Jackling porphyry-copper companies. With an output of 7,500 000 lb. of copper the Utah company is producing at the rate of 90,000,000 lb. a year, while in 1917 the company produced 197,837,111 lb. of metal. Chino is now producing at the rate of 36,000,000 lb. of copper annually, compared with 79,636 000 in 1917. Ray has reduced output 60% below the 1917 rate. Nevada Consolidated's indicated annual output is 56% less than the big war year. These reductions in output will presumably tend to increase the per-lb. cost, but on the other hand it should be remembered that wages and other costs are meanwhile declining, which should therefore off-set this increase. At the beginning of this year, for example, the American Smelting and Refining Co. reduced wages to the extent of 2,000,000 dollars per annum as well as cutting off another 500 000 dollars a year through the curtailment of forces, while it is admitted that the general dropping of prices will greatly assist the supply department. There are reports that arrangements have been made in America for the financing of a part of the stocks, presumably the export-

able surplus. What effect this will have on the market is hard to say.

Average prices of cash standard copper: January 1921, £71. 1s. 4d.; December 1920, £75. 16s. 8d.; January 1920, £118. 4s. 1d.; December 1919, £103. 17s. 1d.

TIN.—The chief feature in this market during the past month was the severe slump in prices of standard tin which took place in the latter part of the month. It is difficult to ascribe the fall to any one particular reason, except that the general demand for tin has been poor, and a considerable amount of liquidation, apparently on the part of tired bulls, appeared on the market, with the result that in the absence of any determined support values lost ground heavily. In the meanwhile no business has been moving in the Straits Settlements where the price remains pegged at the equivalent of £236 per ton delivered to this country. In view of the fact that Straits tin there was well held, the stocks of that grade which are in existence in this country have been fetching a considerable premium over the price of standard tin, this ranging at one time up to £25 per ton. Even, however, when this figure is added on to the price of standard it is very considerably less than the price at which the same material could be purchased in the East. Of course the market for standard, and the market for Straits, have really come to be two different propositions, the bulk of the dealings in the former being based on the stocks of Chinese and English tin, premiums being obtained for both Banka and Australian metal, as well as for Straits, as already mentioned. In view, however, of the severe drop in prices here, there has been a general feeling that some change in policy would have to be adopted in the Straits. The Government there took up the attitude they did with a view to keeping the industry going, and preventing unemployment and discontent. There is, however, a belief that some change will take place at the Chinese New Year, but no news is yet to hand. In the meanwhile a growing demand has been experienced from the Continent, but business with home consumers is slow, and, although a certain amount of trade has been doing with America, on the whole it did not amount to a sufficiently important demand to give any material support to the market.

Average prices of cash standard tin: January 1921, £190. 13s. 11d.; December 1920, £212. 11s. 8d.; January 1920, £376 12s. 8d.; December 1919, £314. 5s. 1d.

LEAD.—During the month of January this market maintained a very steady tone on the whole, and was not so affected by the general depression as were other metals. Copper, tin, and spelter may be said to have fallen to a pre-war level, but lead still remains at a comparatively high figure as compared to what used to be considered normal. This seems all the more surprising in view of the fact that business with consumers has been on a very restricted scale indeed, and the firmness must be chiefly ascribed to the fact that the arrivals coming in recently have been rather reduced. There is a very considerable stock of lead in this country, but this seems to be well held. A part of it consists of the Government stock, which is believed to be partly Broken Hill lead which they appear anxious to conserve for home requirements and are not selling it for shipment abroad. In a manner this is unfortunate, as there has been a good deal of inquiry from the East for this brand which has had to be turned down. Meanwhile, owing to the impossibility of securing Broken Hill lead, the Eastern markets seem to be drawing upon Burma for supplies. Spain does some selling there from time to time, and recently it is understood that some American lead has also been sold there. It must not be forgotten that the world is being deprived of its usual supplies of Broken Hill lead, and this looks like continuing, a serious fire having occurred at the smelting works at Port Pirie, where it is estimated the damage amounts to about £100,000.

Average prices of lead: January 1921, £23. 12s. 6d.; December 1920, £24. 11s. 10d.; January 1920, £47. 7s. 1d.; December 1919, £41. 7s. 8d.

SPELTER.—During the month of January prices of this metal eased off to a certain extent, but on the whole the market kept up a fairly steady tone, this being apparently due to a certain amount of buying being done here on behalf of the United States. There is a big stock of spelter in America, and this buying was solely owing to the fact that the metal could be bought cheaper here than there. Apart from this there has not been very much demand for the metal, the consumption everywhere being very poor on account of the slack conditions in the galvanized sheet trade, and indeed in business generally. In the meanwhile a cer-

tain amount of selling has been seen both by Germany and Belgium, but it is understood that the Belgians are now putting a policy of curtailment of production into effect. The outlook is still rather obscure. It must be admitted that the price of spelter is very moderate indeed, but in view of the general absence of demand it might still be forced lower on account of selling by the Continent. On the other hand consumers are probably very poorly supplied, and when trade revives values would no doubt firm up quickly.

Average prices of spelter: January 1921, £25. 15s. 7d.; December 1920, £28. 11s. 6d.; January 1920, £59. 10s. 4d.; December 1919, £53. 9s. 2d.

ZINC DUST.—This market is very quiet and without much change. High-grade Australian stands at about £70 to £80 per ton, and English at about £70 to £80, while American is quoted at £70 upwards. There is, of course, Continental material offering at less money.

ANTIMONY.—The price of English has been reduced, and now stands at £37 to £40 per ton for ordinary brands, while special brands are quoted at £38. 5s. to £42 per ton. The market for foreign has been easier also, with a good deal of irregularity in quotations. Offers are reported to have been made at down to £24 per ton c.i.f. for shipment from the East.

ARSENIC.—The market is practically stagnant, and the present quotation of Cornish white is about £55 per ton delivered.

BISMUTH.—The price is steady at about 12s. 6d. per lb. with a fair demand.

CADMIUM.—The present quotation is about 6s. 3d. per lb., the market being quiet.

ALUMINIUM.—Prices continue to be quoted at £165 per ton for home and export.

NICKEL.—The price has been reduced by £5 per ton to £210 per ton for home and export.

COBALT METAL.—Unaltered at about 27s. to 30s. per lb.

COBALT OXIDE.—The price of black oxide has been reduced to 16s. and grey to 17s. 6d. per lb.

PLATINUM AND PALLADIUM.—The official price is £19 per oz. for both these articles, but apparently material can be had at around £16.

QUICKSILVER.—The market has been very quiet, at about £12. 10s. to £12. 15s. per bottle.

SELENIUM.—The price continues at 10s. 6d. to 13s. per lb.

TELLURIUM.—The current quotation is 90s. to 95s. per lb.

SULPHATE OF COPPER.—The market is quiet and without much change, the present price being quoted at £38 to £40 per ton.

MANGANESE ORE.—The quotation is about 2s. 1d. to 2s. 2d. per unit c.i.f. U.K. for Indian grades, but this is more or less nominal in the absence of business.

TUNGSTEN ORES.—There is little or no demand, and the present price of wolfram is about 15s. 6d. to 16s. 6d. per unit c.i.f.

SILVER.—On January 3 the price of spot standard bars was 41⅞d., this figure rising to 42½d. on the 5th. Subsequently quotations fluctuated, with a downward tendency, the figure at the end of the month being 35⅛d. per oz.

GRAPHITE.—Soft velvety flake 85% to 90% stands at about £60 to £80 per ton, and Madagascar 80% to 90% at about £21 to £25 per ton.

MOLYBDENITE.—85% is quoted at about 65s. on spot and 55s. for forward per unit c.i.f. U.K.

CHROME ORES.—48% to 52% stands at about £7. 10s. per ton c.i.f.

IRON AND STEEL.—The fall in prices which has been so long expected is now beginning to take more tangible shape. Prices of Cleveland pig iron were reduced and now stand at £9. 15s. to £10 per ton for No. 3 foundry. East Coast hematite has also come down to 220s. with No. 1 at 2s. 6d. per ton more. These reductions do not appear, however, to have stimulated very much business, and consumers everywhere appear to wait for still lower prices, and in this it does not look as if they would be disappointed. Prices of certain descriptions of steel and manufactured iron have also come down, but in no case does very much fresh buying seem to have been stimulated, the fact being that Continental prices are still very considerably lower. With general world trade conditions in the stagnant condition they have been, it is useless to expect any activity in this particular branch of industry, and in any case, with further price reductions apparently inevitable, it was hardly to be expected that any buying of importance would develop.

THE MINING DIGEST

A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also reviews of new books, and abstracts of the yearly reports of mining companies.

KIRKLAND LAKE GOLD MINING DISTRICT.

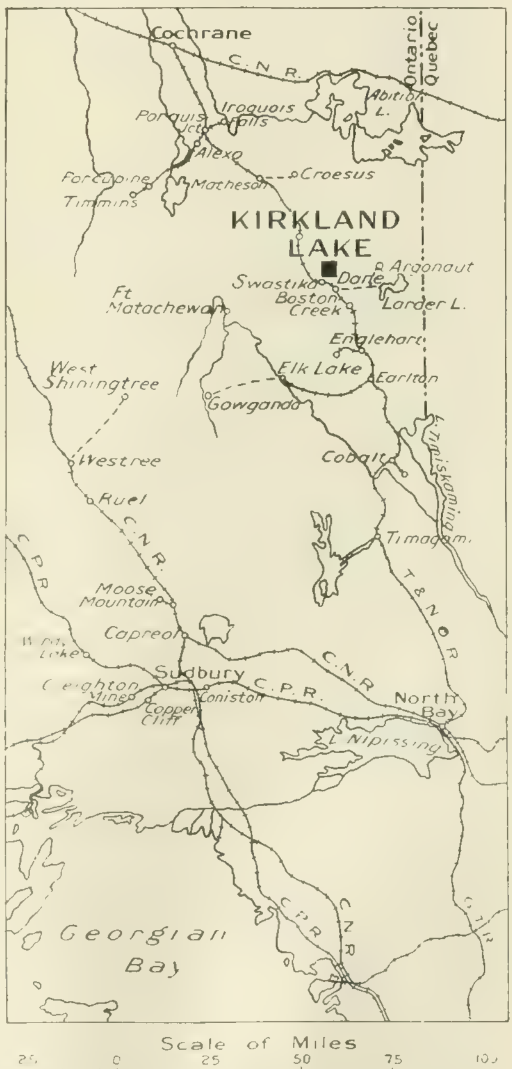
The Ontario Department of Mines has issued a report on the Kirkland Lake gold area by A. G. Burrows and P. E. Hopkins. As this is the fourth most important precious-metal producing district in Ontario, we give herewith lengthy extracts on the general geology and ore deposits. Next month we intend to reproduce the details relating to the individual mines. Reference to the history and development of the district is made in the editorial pages this month.

The Kirkland Lake area is situated a few miles south of the divide between the Hudson Bay and river St Lawrence waters. The lake has an elevation of 1,038 ft. above sea-level and no hill apparently rises more than 100 ft. above that level. There are rock outcrops over most of the area. The small proportion of drift is usually sand, thinly distributed. The mineral deposits are frequently found in the lower parts of the area, since the fractured zones and adjoining altered rocks are more easily eroded than are those that are less fractured and less altered. The porphyry apparently weathers down more easily than the other rocks. The area is part of a large mineralized region that extends roughly from Matachewan in the south-west to Larder Lake and beyond into Quebec province to the east. In places the older gold-bearing rocks are covered by deposits of newer formations, conglomerate, greywacké, and slate of the Cobalt series, which have not been removed by erosion and consequently cover possible gold deposits. The character of the gold deposits varies greatly in different parts of the larger area, but all occurrences are believed to be associated with the acid intrusive rocks of a granite, syenite, and porphyry character that frequently outcrop in various parts of the area.

General Geology.—The compact rocks are Pre-Cambrian, classified according to the following table, the oldest being placed at the bottom and the others in the order of their relative ages.

KEWEENAWAN (?) ...	Quartz diabase and olivine diabase.
POST-TIMISKAMING INTRUSIVES (ALGOMAN ?)	Red and grey felspar-porphyry with subordinate amounts of hornblende-syenite and felsite occurring as dykes and stocks.
	Red hornblende-syenite.
	Black mica lamprophyre grading into or cut by red, hornblende syenite, the latter being felsitic or porphyritic in places.
	(The above three groups of rocks are differentiation facies from the same magma).
	Serpentine.
	Hornblende and biotite granite and gneiss, syenite, granite-porphyry, felspar-porphyry, felsite, pegmatite and hornblendite.
TIMISKAMIAN ...	Schistose conglomerate greywacké and quartzite containing some carbonate schist.
	Rusty carbonate.
KEEWATIN	Pillow lava, altered diabase, green schists, rusty carbonate and iron formation.

The Keewatin, which is the dominant rock in the region, occupies only a small portion along the north and south-east sides of the area. These rocks are chiefly basalt and diabase, volcanic rocks which have flowed out under the sea, with subordinate amounts of iron formation, rusty carbonate, and other rocks. Lying unconformably on these rocks and interfolded with them is a band of Timiskamian sediments which occupies most of the area. These fragmental rocks are two miles in width, and extend to the south-west and to the north-east for several miles. After the deposition of the sediments, extensive folding and metamorphism took place. Later the sediments were cut by a number of intrusives, namely: granite, syenite, serpentine and



MAP OF PART OF ONTARIO, SHOWING POSITION OF KIRKLAND LAKE

related lamprophyre, syenite, and felspar porphyry. The gold deposits are genetically connected with the porphyry. All the rocks, including the ore bodies, have been intruded by diabase dykes of Keweenawan age. These Pre-Cambrian rocks may have been covered by Palæozoic rocks, but no erosion remnants are to be seen at present. The glaciers which passed over the whole region have scraped away any decomposed rock from the surface and carried it southward, leaving the rocks and mineral deposits exposed as we find them. In places the rocks are still covered with a thin mantle of glacial sand and gravel.

Origin and Age of the Gold Deposits. — All the gold deposits of northern Ontario are in the Pre-Cambrian, in rocks which, with few exceptions, are older than the Cobalt series. After the folding of the Timiskaming series and before the deposition of the Cobalt series, there was a period of igneous activity during which basic and acid rocks, including lamprophyre, porphyry, syenite, and granite, were intruded into the older rocks. The probable genetic relationship of the gold deposits of Porcupine to granite intrusions has been noted in a report on that area. There are a number of gold-bearing veins at Kirkland Lake associated with felspar-porphyry and syenite, suggestive of a relationship between the intrusives and the veins. There are areas of granite and syenite within a short distance of the gold deposits. An examination of a number of specimens from these plutonic areas shows that these rocks contain albite, usually as phenocrysts, similar to the felspar-porphyry. It is quite likely that the granite, syenite, and felspar-porphyry belong to the same period of intrusion and are different facies of a magma which underlay or underlies a large part of the area. The syenite and granite have been exposed by deep erosion.

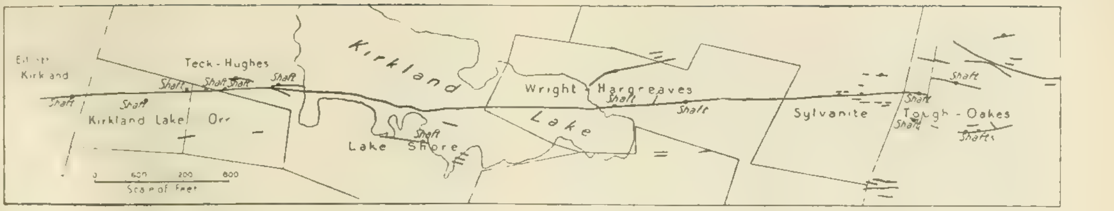
While the gold-bearing veins were formed subsequent to the intrusion of the porphyry, it is likely that they are genetically connected with the intrusive rock which occurs as dykes and boss-like masses. The cooling of the intrusive was apparently accompanied by shrinkage, faulting, and displacement in the porphyry itself and in the adjacent rocks. The gold-bearing silicious solutions that deposited their burdens in the fissures and other fractures in all probability represented the end product of the intrusion of the acid rocks that have been mentioned.

Lindgren, in his classification of mineral deposits, places the gold-quartz veins of Ontario in the division of "veins and replacement deposits formed at high temperature and pressure and in genetic connection with intrusive rocks." He says: "These veins are clearly related to those of the southern Appalachian states, but, on the other hand, they present some remarkable analogies with those of California." These veins were formed at considerable depth and have been exposed by extensive erosion, but it is probable that they were not formed at as high temperatures as the veins at Porcupine, in which tourmaline and pyrrhotite frequently occur. The minerals tourmaline, pyroxene, garnet, amphibole, and biotite, characteristic of deposits formed at high temperatures, have not been recognized by the writers in the Kirkland Lake area. Albite, chlorite, sericite, and carbonates are present in the deposits as alteration products. The veins at Kirkland Lake in their mineral constituents greatly resemble those of the Sierra Nevada, California, which are described by Lindgren. In these latter veins tellurides like altaite, hessite, calaverite, petzite, and melonite are frequently associated with native gold. In a comparison of the Cripple Creek and Kalgoorlie gold deposits, Lindgren has shown that telluride of gold may be deposited in large quantities both near the surface (as at Cripple Creek), and at a depth of many thousands of feet below it (as at Kalgoorlie). Telluride of gold is not so abundant in the Kirkland Lake deposits as telluride of lead, but probably occurs in greater quantity than has been suspected owing to the difficulty of identifying the telluride in fine grains when accompanied by native gold. As stated above, the mineral associations at Kirkland Lake are not typically those of high temperature deposits. Magnetite has been found in gold-bearing veins at the Argonaut mine, a few miles east of Kirkland Lake, and specularite has been reported in veins from the Tough-Oakes mine. The Kirkland Lake deposits have probably been formed at considerable depth, like the Kalgoorlie deposits, but not at such high temperatures, while the mineral association is somewhat similar in that native gold accompanies the tellurides.

Distribution of Ore Deposits. — Exploration in the Kirkland Lake area has indicated three principal zones of mineralization. The main or central zone is that which runs north-easterly and south-westerly along the southern expansion of Kirkland Lake and along which a group of mines is being developed over a distance of 2¼ miles. The principal mines of the area, Tough Oakes, Burnside, Sylvanite, Wright-Hargreaves, Lake Shore, Teck Hughes, Orr, Kirkland Lake, and also several prospects are situated along this zone. A southerly zone lies about ¾ mile to the south with a similar strike, and along it are the Ontario-Kirkland, Hunton, Honer, and Canadian-Kirkland, on which considerable work has already been done. A northerly zone, known as the Goodfish Lake gold area, lies about two miles north of the central zone, where a number of properties, including the Costello, La Belle Kirkland, and Fidelity, are located.

Kirkland Lake Mineral Zone. — The greatest amount of work has been done on the central zone, where a number of gold bearing veins have been discovered extending over 2¼ miles in length and a width of ½ mile. In this zone operations have shown a major fracturing along which the principal properties are located. It is believed that, after the intrusion of the porphyry and syenite, faulting took place in lines roughly parallel with the long axis of the intrusions, accompanied by fracturing and crushing of the porphyry and other rocks with the formation of the veins or lodes along these fracture planes. The principal or major fracturing can be traced across a number of properties where ore-shoots are being developed at widely separated points, but evidently along one system of fracturing. This fracturing has crossed all the different rocks in this zone, including felspar-porphyry, syenite, lamprophyre, and conglomerate. No. 1 vein at the Kirkland Lake mine, No. 2 vein of the Orr, No. 3 vein of the Teck-Hughes, No. 2 vein at the Lake Shore, and No. 2 vein at the Wright-Hargreaves are being developed along the major fracturing. In addition there are branch veins and other fractures roughly parallel, on which development has been done on a number of properties; examples are No. 1 vein at the Lake Shore, Nos. 1 and 5 veins at the Teck-Hughes, and No. 1 vein at the Wright-Hargreaves.

The fault planes along which the ore deposits have been formed dip to the south, usually at a high inclination, 80° to 85°, although locally there are rolls in the fault planes that are steeper or flatter than the average dip. A fracture zone will contain several fault planes, which often form the boundaries of ore, and at several mines development has been carried on with regard to two prominent fault planes called foot-wall and hanging-wall planes. These planes are from a few feet to 40 ft. or more apart, the ore sometimes occurring over this whole width, or, as is more frequent, near one or the



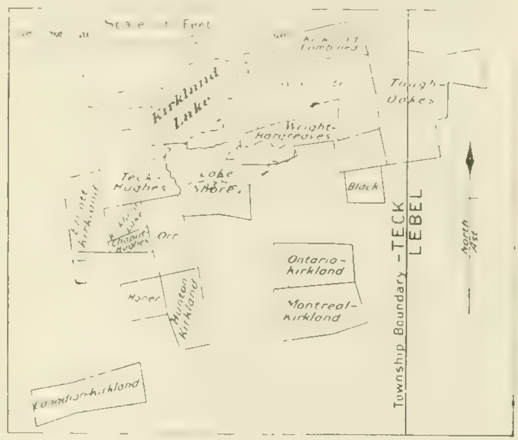
MAP SHOWING PRINCIPAL WORKINGS AND LODES AT KIRKLAND LAKE.

other wall, depending on subsidiary slip or fault planes. The ore will also at times extend beyond the recognizable fault planes or so-called vein boundaries.

The faulting and fracturing of the rock has permitted the circulation of mineral-bearing solutions with accompanying vapours, which have partly filled any open fissures and partly replaced the country rock in the fracture zone. The amount of vein quartz in the ore deposits is relatively small as compared with the mineralized porphyry or other rock through which the fractures have extended. In addition to irregular masses of quartz several feet in width that occur along the veins, there are numbers of narrow irregular quartz veins a few inches in width penetrating the porphyry or other rock, together with mineralized or replaced rock, which make up the ore-body. In consequence of the irregular distribution of quartz in the veins the working faces along drifts on the veins vary greatly in appearance, sometimes showing considerable quartz and at other times almost entirely mineralized porphyry or other rock with minute veinlets of quartz intersecting it.

The mineralization of the veins has extended over a long period, since there has been repeated fracturing along the mineralized zone. The primary quartz is greatly brecciated, and fragments of quartz and porphyry have been displaced along the fault planes. Movement along the walls in the ore-bodies is evidenced by grooving and slickensided surfaces in the direction of movement. Information as to the extent of horizontal displacement may be obtained at the Teck-Hughes mines, where a north and south dyke of diabase 60 ft. in width has been faulted a distance of 150 ft. along No. 3 vein, the part of the dyke to the north of the fault planes being to the west. Several large blocks of diabase occur in the fracture zone together with masses of crushed porphyry or syenite thrust along the fault planes. Mineralization even later than this extensive movement is indicated by the presence of gold values along slip planes in fragments of diabase in the fault zone. The unaltered diabase itself does not carry gold values.

Mineralization of Porphyry and Syenite.—There has been an extensive mineralization of porphyry and syenite in parts of the area that extend through the southerly part of Kirkland Lake. This is apart from that mineralization which occurs with the commercial ore-bodies. The long cross-cuts connecting Nos. 1 and 2 veins on the 200 ft. and 400 ft. levels at the Lake Shore mine are through these rocks. The assay plans show numerous assays of gold from traces up to 40 cents with occasional higher assays of rock in the cross-cuts. This rock when examined closely is seen to carry minute veinlets of quartz with disseminated iron pyrites, which would account for the frequent gold values. Similar low values are shown in cross-cuts at other properties away from the veins, indicating a general mineralization of much of these intrusives away from the recognized veins. This mineralization is probably dependent on the faulting and fracturing previously referred to along the central zone, and not, as



PLAN OF MINING PROPERTIES AT KIRKLAND LAKE.

might at first be supposed, due to a gold distribution at the time of the crystallization of the intrusive rock.

Character of Gold Deposits.—The early development of the Kirkland Lake area was chiefly at the Tough-Oakes mine, where a number of narrow gold-bearing veins were discovered. The most important was No. 2, which, at the surface, carried extremely high-grade ore over a width of 2 to 6 in in the conglomerate, the vein fissure being largely filled with quartz. Development proved that the vein ran from the conglomerate into the porphyry on the surface and at depth, and by far the greater part of the gold extraction has come from the ore-shoot in the porphyry. While the high-grade quartz vein in the conglomerate carried most of the values with mill ore in the wall-rock affording a narrow compact ore deposit, when it entered the porphyry the quartz occurred usually in narrower veinlets spread across a greater width with much fracturing of the porphyry along the vein. Consequently most of the ore in the porphyry is fractured porphyry with numerous slip planes, along which quartz, calcite, and ore-bearing minerals have been deposited, affording a greater width of ore than in the conglomerate. The stopes on the vein average about 5 ft. in width. Development on other veins on the property also indicated that they contained narrow ore-bodies either in the porphyry or greywacké and conglomerate

The early exploration farther west along the mineralized zone did not meet with such satisfactory results, the veins in the conglomerate and porphyry along the surface not showing such high-grade ore as occurred at the Tough-Oakes, with the exception of the north vein at the Wright-Hargreaves, which produced a small amount of high-grade ore when it was operated for a short time in 1913.

The main fracture zone, or main vein, which for most of its length is in low ground or under the bed of Kirkland Lake, was difficult to prospect, and only after

several years of work has it been proved to be the locus of the principal ore deposition. Much of the previous work was done on parallel or subsidiary and narrower veins. In the main fracture the ore deposits have been found to be wider than had been expected, reaching in places 40 ft. in width, but as a general rule running from about 5 ft. to 15 ft. in width.

Strictly speaking the ore-bearing deposits should be called lodes or composite veins formed under strong compressive forces, with the solutions following openings along fracture planes in an irregular manner and partly replacing the country rock adjacent to the fractured planes. The stringers and masses of quartz intermingled with the fractured porphyry or other rock generally lie in the direction of the vein or lode, but are often connected by transverse stringers. The replacement character of the ore is frequently recognized by masses of quartz spotted with remnants of red porphyry; this ore has a faint reddish colour due to the included porphyry. In other cases masses of ore are bright red porphyry or syenite with very thin seams of quartz that are hardly recognizable. The lenses of quartz are sometimes several feet wide in portions of an ore deposit and contain much visible gold together with tellurides, pyrite, copper pyrites, molybdenite, etc. Some of the ore shows very little vein quartz, and specimens of altered red syenite from the Lake Shore mine have been found to contain grains of gold in the secondary minerals, calcite, and sericite intermingled with the original felspars of the rock. Mining operations at the Kirkland Lake mine, October, 1920, have indicated promising ore at a depth of 900 ft. where the same general mineralization has been encountered.

Minerals in Kirkland Lake Veins.—The oldest mineral in the veins, apart from the rock-forming minerals, is a coarsely crystalline quartz. Usually this quartz has been broken up and other minerals deposited in the fracture planes. Of these there is quartz, often of a somewhat darker colour than that first deposited. Carbonates of various composition are present in the veins. A pink carbonate proved on analysis to be calcite with 5·34% of magnesium carbonate; a grey variety is ankerite. There have been different periods of fracturing. Some of the quartz is later than the carbonates. Where there have been inclusions of country rock in the vein and replacement, some sericite has been developed. Chlorite also occurs as a vein material. Iron pyrites is the most abundant of the sulphides, being found both in the wall-rock and in the veins, usually in well crystallized forms. Some of the pyrite in the vein is in fine grains. Copper pyrites occurs to some extent, generally where the vein is gold-bearing. Galena and zinc blende occur in very small quantity. The latter material has been observed in small incrustation veinlets, which are later than the ore. Molybdenite has been deposited abundantly in fractures, usually as a thin film. Graphite has been recognized in some of the ore. This mineral, when in thin films, is difficult to distinguish from molybdenite. Crushed iron pyrites along slip planes has also produced a bright blackish deposit that resembles molybdenite or graphite. Gold-bearing solutions have circulated along these planes, and the veins have been enriched by the deposition of gold in these later fractures. Later movements have often occurred along these planes, and the gold, altaite, and other tellurides, pyrite, copper pyrites, molybdenite, and graphite deposited along the planes have been crushed and polished or slickensided. In some cases the gold has been deposited after the slickensides have been formed, since veinlets of the metal have been observed on the 200 ft. level of the Tough-Oakes mine cutting across the smooth planes of the molybdenite. One of the latest minerals with white calcite along fault planes is barite of a deep red colour, observed at the Teck-Hughes and Lake Shore mines.

Several tellurides have been recognized in ore from the Kirkland Lake area. The most abundant telluride is altaite (PbTe), telluride of lead, which has been recognized in ore from all the mines in the central zone. This mineral is readily recognized by the well developed cubical cleavage and brilliant cleavage planes. It has a very faint greenish tinge, which aids in recognizing it in fine grains. This mineral is usually accompanied by visible gold and its presence often indicates high-grade portions of the vein. Telluride of gold, calaverite ($AuTe_2$), has only been recognized in ore from No. 3 vein at the Tough-Oakes mine. Specimens from this vein show calaverite in quite coarse grains and readily recognizable. The mineral is of a pale brassy, almost white colour, brittle and quite soft. It resembles pale-coloured iron pyrites, but is much softer. The mineral on assay yielded 40·6% gold. This mineral is probably sparsely distributed in the ore, but if in very fine grains would be difficult to recognize in hand specimens. Black tellurides carrying mercury have been recognized recently in specimens from the Tough-Oakes mine. One of these corresponds to kalgoorlite, a telluride of gold, silver, and mercury. An analysis of selected material by W. K. McNeill gave the following composition: Au 20·40%, Ag 31·1%, Hg 10·2%. Another telluride contains mercury and tellurium with no gold or silver and is coloradoite. These mercury-bearing tellurides were definitely recognized in polished surfaces by means of the microscope and by chemical and blow-pipe tests. A mercury telluride, probably coloradoite, also occurs in specimens of ore from No. 2 vein at the Lake Shore mine. The mineral is here associated with native gold, altaite, pyrite, and copper pyrites. The tellurides, tetradymite (telluride of bismuth), and hessite (telluride of silver), have been reported from No. 2 vein of the Tough-Oakes mine, but have not been recognized by the authors.

Examination of a number of thin sections of ore from the Kirkland Lake area shows that the vein material has been much brecciated. Fragments of porphyry, syenite, conglomerate, or greywacké, depending on the character of the wall-rock, are enclosed in vein materials, which are chiefly quartz with calcite and dolomite. Replacement of the various rocks by quartz is also in evidence. The coarsely crystallized quartz of the first generation is fractured, and the fracture filled with later quartz, calcite, and dolomite. The principal sulphide and telluride minerals occur chiefly with the finer-grained material in the minute fracture planes in the quartz and altered rock. An interlacing meshwork of metallic sulphides and tellurides with native gold is frequently observed. Wherever the tellurides occur, native gold is usually recognized in grains close to the telluride grains. Grains of gold are seen in the tellurides, and again minute veinlets of gold sometimes traverse coarse masses of telluride. The crystallized calcite frequently contains gold that has been deposited along the rhombic cleavage planes. The contact of fragments of porphyry or other rocks with quartz is usually a place for concentration of the sulphides, tellurides, and gold. Replacement of the rock is recognized by a gradual transition to quartz and other later minerals. Native gold has been observed in contact with telluride, molybdenite, pyrite, and copper pyrites. A section of high-grade ore from the Kirkland Lake mine shows quartz in contact with altered syenite. There is a concentration of pyrite and tellurides with gold along the contact of quartz and rock and also in the quartz, which is fractured and carries fine-grained

quartz and calcite in the fracture planes. There is abundant sericite and carbonate in the altered rock. A blackish mineral in very thin films is believed to be molybdenite. A sample of high-grade ore from Kirkland Lake mine, containing 21·42 oz. of gold per ton, has the following partial composition: Fe 1·65%, MoS_2 0·34%, S 0·65%, C 0·09%, Te 0·10%. This analysis shows the presence of both molybdenite and graphite in the ore.

(To be continued).

SULPHUR IN SOUTH AFRICA.

The *South African Journal of Industries* for November contains a report by T. G. Trevor, Inspector of Mines, on the production and consumption of sulphur in South Africa. The demand for sulphur in South Africa is great, both in its elemental form for vine dressing, etc., and as sulphuric acid for the manufacture of explosives, fertilizers, and many other at present smaller chemical industries. The imports in 1917 were: sulphur, 899 tons; pyrites, 18,465 tons; sulphuric acid, 37,435 lb. The prices were approximately £10 per ton for sulphur, £3. 9s. for pyrites, and 4½d. per lb. for sulphuric acid. In 1913, before the war, the quantities were as follow: sulphur, 2,672 tons; pyrites, 22,903 tons; sulphuric acid, 291,976 lb. The following were the approximate values: sulphur £6. 8s per ton, pyrites £2. 13s. per ton, sulphuric acid 4 2d. per lb.

In 1918 it was reported that there were three explosives factories, one chemical, and one fertilizer works in the country, which were producing sulphuric acid for their own needs, producing it for trade when they get the necessary pyrites and convenient railway facilities. Two large by-product works were then starting and more will doubtless follow; these also will need either to buy or to make their own acid. The names and addresses of the above-mentioned works and the essential details about them in August, 1920, are given in the accompanying table. The Cape Explosives Company do not at present accept gold-bearing pyrites. The other companies purchase the gold contents at their current value less certain agreed charges. It will be seen from the table that the present demand for pyrites is 1,650 tons per month, and in fifteen months' time it may be 3,500 tons. It is more than likely that this demand will increase by leaps and bounds, for the enormous quantities of low-grade cheap coal in the country, which contains a high percentage of nitrogen, is already attracting world-wide notice, and, given a cheap source of sulphuric acid, the fertilizer industry is capable of indefinite expansion; other industries also are daily springing up, most of which need the acid. It is therefore necessary to study the question of the possible sources of supply.

Native sulphur occurs in small quantities, probably as a product of the decomposition of pyrites, in the cavities of honeycombed quartz in the mines of Pilgrims Rest. It has also been found occurring in some of the rocks of the coastal belt near Port St. Johns, but so far as is known neither of these occurrences is, or is likely to be, of any commercial importance. From the coastal plain at Walvis Bay a sample of native sulphur, a few pounds in weight, has recently been received by the Geological Survey Department. This appears to be native sulphur mixed with sand. It burns freely, and evidently contains at least 50% of sulphur. It is said to occur from Walvis Bay southward to Conception Bay in surface agglomerations in the same sands that carry the diamonds. The occurrence was brought to the knowledge of the De Beers Company some years ago, but that company did not interest itself in it, considering the quantities to be too small, though its agents estimated that some 90 tons might be collected from the visible deposits. The occurrence, however, has not been scientifically investigated, and, in view of the extraordinary developments which have attended the following of somewhat similar surface occurrences in Texas, it certainly merits closer attention. For the time being, however, it must be admitted that the Union is void of any known deposit that is likely to develop into a profitable sulphur mine.

Up to 1915, when the war began to curtail the supply of foreign sulphur and pyrites, there had never been any demand or inquiry for pyrites in South Africa, with the result that no one had ever sought for it, or recorded its occurrence if found in prospecting for other metals. A lode or deposit of massive pyrites never appears on the surface, except as an outcrop of barren ferruginous gossan. There are many such known to the author in the Transvaal, and there must be many more, but, as they show nothing in the pan to the prospector, and as pyrites of itself was formerly of no value, they have never been opened, and, with one exception, no massive pyrites is yet known in the Union. The exception mentioned is the Areachap copper mine, situated some

28 miles from Upington and 10 miles from the railway. This mine was discovered in 1906 and closed down in 1909. It was reopened on the advent of the railway to the neighbourhood in 1916, but again closed down in 1917. In the first period an attempt was made to run the Areachap solely as a copper mine. In the second period attempts were made to establish a trade in pyrites. Some few hundreds of tons were supplied to the explosives factories, and the ore was found to be entirely suitable for burning, but the expenses were so great that there was no profit in it for the mine. If a railway siding were constructed to the mine, which could be done at an estimated cost of £17,000, and the mine were properly developed and equipped, it seems well within the bounds of possibility that the mine would prove to be the permanent and reliable source of pyrites which is needed; but in the meantime the railway waits on the development of the mine, and the mine waits on the construction of the railway.

The average of assays of Areachap ore delivered to Messrs. Kynoch in 1916 was sulphur 38·9%, and arsenic 0·11%, but in many other assays the arsenic appears as nil. On the surface the outcrop of this lode shows as a ferruginous gossan of great extent, being 50 ft. wide and 1,450 ft. in length. Small masses of native copper and some nodules and bunches of copper sulphide occurred in this gossan. A main shaft was sunk to the depth of 295 ft. and several other shafts to lesser depths, but no iron pyrites was found above the 200 ft. level. Down to that level the ore was completely oxidized to gossan. The iron pyrites begins at 200 ft., and at 223 ft. the lode, inclusive of some horses, is said to be 50 ft. wide and to consist of massive pyrites assaying 39% sulphur. Such a mass of pyrites would, under ordinary circumstances, be of great value, but, situated as it is—10 miles from the railway and more from fresh water and many hundreds of miles from anywhere where the product can be economically used—it has so many difficulties to overcome that the price of the pyrites at the point of use can never be as low as is desirable in competition with the imported article.

Though the Union is, for the present at all events, void of satisfactory workable deposits of massive pyrites, yet disseminated pyrites is common throughout all the older formations, and plentiful in all the gold-bearing rocks and in most of the coal mines. It is from these sources that the present local supply of pyrites for the South African factories is being derived, and this source of supply seems to be capable of great expansion to the advantage of the gold and coal mines.

The coal in the working coal mines of the Transvaal and Natal contains an average of about 1·5% sulphur in the form of pyrites; this equals say 3% pyrites. For the ordinary coal trade it is not necessary to eliminate this, but for making metallurgical coke it is imperative that the coal should have as low a sulphur content as possible. One large and several small coking plants are now being erected, and the demand for coke by the Pretoria iron mines alone, on the estimated output of 300 tons of iron per day, will be some 350 tons per day—say 10,500 tons per month. This coke will take for its formation—including the loss in sorting and washing—probably 18,000 tons of coal. Over and above the demands of the Pretoria iron mines it is likely that there will be an almost equal general demand, and it will not be an exaggeration to say that in the course of the next year or two 30,000 tons of coal per month will be coked in the country. Allowing that half the pyrites, or say 1·5%, is recoverable in the washing plants, this will yield a supply of some 450 tons of pyrites per month, and, as this will be a by-product, its cost to the acid factories should be well within the economic limits.

All the gold ores in the country, with the exception of the free-milling ores in the oxidized outcrops, are charged with disseminated pyrites, and this pyrites invariably carries a considerable proportion of the gold. In the banket reefs of the Rand, this amount is commonly about 3%, and about 2·5% could be reckoned on in the tailing dumps. This pyrites also carries a considerable value in gold, though it is a mistake to consider that all the gold lost in the tailings is contained in it. The author is informed that some years ago Professor Stanley investigated the question of concentrating these dumps and extracting the sulphur and gold from the concentrates, but came to the definite conclusion that in so far as the Main Reef dumps went it was not a payable proposition. On the Black Reef, however, near where the outcrop of the reef is crossed by the Natal Spruit, there were several old mine dumps which contained upwards of 20% sulphides, and in the Klerksdorp district the Machavie mine gave an ore carrying an equal amount. For the last ten years and more this source of supply has been drawn upon by the New Transvaal Chemical Company for their sulphuric acid works, and latterly some has also been supplied to Kynochs and the Natal Ammonium Company. Unfortunately the dumps are now worked out and the supply from the Machavie mine became too costly, and that mine has had to close down. About 1906 the so-called Sandstone Reef at the Sabie was discovered. This is an interbedded quartz reef in the sandstone lying between the Black Reef and the dolomites. Usually it is up to 3 ft. in width and carries up to 7 dwt. gold and 25% pyritic material. A good many small mines have since then been worked on this reef.

In 1916 the surviving mines, which had been worked with some small degree of success by their owner-managers, became aware of the possible value of the pyrites in their tailings, and negotiations were entered into with the explosives companies. A good deal of difficulty attended these negotiations; the owners did not wish to go to the expense of concentrating plants unless the explosives companies would contract to buy the concentrates; the explosives companies did not wish to alter their plants to burn fines or to accept a contract unless they were first satisfied that the other parties were really in a position to keep their contract over a period of years. This difficulty has now been overcome, and the following mines are turning out a regular supply, much to their profit, and other mines are preparing to do so too: Ceylon-Lydenburg, 67 tons pyrites per month; Buchanan Syndicate, 156 tons pyrites; Jollie Bright, 105 tons pyrites. These figures are for July, 1920. The terms on which the concentrates are purchased are approximately as follow: The purchasers pay 30s. per short ton for concentrates carrying 45% sulphur f.o.r. Sabie; the gold contents to be extracted by the purchaser and to be the property of the sellers, 6s. per ton being deducted for extraction charges. All by-products which may be discovered in the pyrites to be shared equally by both parties. As these concentrates usually carry over 10 dwt. of gold, and in many cases double that quantity, it is obvious that this demand for pyrites has been very much to the advantage of the mine-owners, who are receiving 64s. per ton or more for concentrates which were formerly lost, merely at the additional cost of concentration, which must equal a value of about 10s. to 12s. per ton on the rock crushed, and this advantage has enabled them to continue working profitably when otherwise the increased cost of stores, etc., in the past two years would probably have led to some of them at least clos-

ing down. It is probable, however, that the explosives companies, though their position has been greatly relieved by the local supply of pyritic sulphur, are not in such a satisfactory state as they were before the war, and that for a long time a struggle will go on between the consumers and the producers before a stable price is arrived at. The Rietfontein mine, though not on the Sandstone Reef, produces, say, 5% concentrates carrying up to 3 oz. of gold to the ton. This mine formerly had great difficulties with its extraction, but these have now been overcome by selling the concentrates on terms similar to the above.

In 1919 these mines were supplying about 400 tons of pyrites per month. This supply can, and probably will be increased to about 1,000 tons, but even then the present demand, which is not less than 1,650 tons, will not be satisfied, and the question must be asked how can this deficit be made up and provision for the increased demand which is sure to arise be made Failing the discovery of massive pyrites it is possible that the demand may be met by the mines of the Barberton district. Practically all the mines of that district are pyritic, and there are many reefs and deposits which have never been worked because they were so pyritic that there was little chance of their paying as free-milling propositions. The Sheba mine of late years has been entirely a concentration proposition, and about 300 tons of concentrates were produced monthly, but the local treatment was not profitable. The mine has now reopened, and is, or shortly will be, again in a position to produce these concentrates, and if these can be sold somewhat on the same terms as those from the Sabie the question of the payability of the mine will be largely solved. Unfortunately, however, these concentrates contain a considerable percentage of arsenic, which is almost absent in those from the Sabie, which contain only 0·01 to 0·14%, and the consuming companies are loth to use it, as so far they have been able to either import or obtain locally pyrites low in arsenic. For the contact process it is true that arsenic is very undesirable, as even very small quantities have extremely detrimental results, and must be eliminated during the process; but for the chamber process there are quite sufficiently satisfactory dearsenicating processes which are not particularly costly, and it appears that when once pyrites containing 1% or so of arsenic is accepted, a supply quite equal to the demand might be obtained from the Barberton district. Unfortunately the claims in this district are all in the hands of small men, who cannot afford to develop on pyrites unless they can first get a firm offer for their product. The consumers are not likely to give this, and in order to give it go to the preliminary expense of adding a dearsenicating process to their plant, unless they are certain of a fixed and reliable supply. The properties at Barberton, which the author has in mind as possible producers of auriferous pyrites, are as follow: (1) Mount Morgan mine, Moodies; concentrates 15% to 29%, gold in original ore believed to be not less than 8 dwt. (2) North Star mine; concentrates 20% to 25%, gold in original ore believed to be not less than 5 dwt. (3) French Bobs mine; concentrates 25% to 30%, gold in original ore believed to be not less than 4 dwt., much arsenic, etc. (4) Golden Hill claims; concentrates 20%, gold in original ore believed to be not less than 5 dwt. (5) Eagles Nest mine; portion carries 20% concentrates, gold in original ore believed to be not less than 5 dwt. But, among the old and abandoned claims, which were abandoned because there was too little gold and too much pyrites, and of which no record has been kept, there must be many others, and the subject is one which he believes would thoroughly repay investigation *in loco* by any of the prospective consumers. It will not be sufficient for them merely to express their desire for such concentrates and to wait until sellers come forward with them, for mining in Barberton is at such a low ebb at present that there are not enough well-to-do miners and prospectors left to take advantage of such an offer. It will be necessary to send a competent engineer to the district to investigate every deposit that can be heard of and to make arrangements for having such proved as seem most suitable. It will be impossible to embark on any scheme of development otherwise.

REPAIRING LENS COLLIERIES BY CEMENTATION.

In December, H. Standish Ball read a paper before the South Wales Institute of Engineers on the Francois cementation process as applied to mining. In the course of this paper the author described the repairing of shafts in the Lens district in northern France after the retirement of the German armies.

As a result of the British victory on the Vimy Ridge on April 9, 1917, a large number of the collieries in the neighbourhood of Lens were recaptured from the Germans, and a military engineer was immediately instructed to carry out an investigation and ascertain whether there was an underground communication with Lens, that town being still in hostile hands. Fosse 11 was the first pit examined within a few days after the German retirement. On reaching the heap of débris representing the surface plant a roaring sound was heard, apparently proceeding from the depths of the shaft. A small party was formed, and after some difficulty succeeded in descending the shaft for a certain distance. The noise was found to be caused by water pouring through a cavity in the tubbing some sixteen feet square. Through this cavity the water was pouring at the rate of many thousand gallons a minute. The break in the tubbing occurred about sixty yards from the surface, and some distance below the permanent chalk water-level. Traces of German handiwork were apparent, being represented by a kibble used by their demolition party, electric leads, &c. So rapidly were the workings of the mine flooded that, in spite of the shaft being some 340 yards deep, the water rose to the chalk water-level within the space of a few days. On measuring the water-level in several other pits the rise was found to be constant, proving that all the eighteen pits of the Concession de Lens were flooded; it was therefore thought probable that other shafts had been treated in a similar manner to the one mentioned. This was found to be the case, and negotiations were immediately entered into by the French Government with various English firms to supply pumping machinery for the unwatering of these pits when once the breaks had been sealed off.

Soon after the conclusion of hostilities Monsieur François was entrusted with the work of repairing several of the shafts. By means of suitably placed bore-holes and injections of cement under high pressure the water flowing into these shafts was sealed off in a comparatively short time, and the ultimate recovery of the coal greatly expedited. The procedure adopted in the cementation of each pit differs little in detail; it is therefore only proposed to deal with pit No. 11. When the pit was originally sunk, a very large horizontal fissure was encountered at a depth of 63 yards, a certain amount of difficulty being experienced in dealing with the great amount of water. This fact

was taken advantage of by the Germans, for a charge was exploded in the shaft at the exact depth of the fissure, causing holes 16 ft. by 22 ft. and 19 ft. by 13 ft. to be blown in the sides. The resulting rush of water has been already mentioned, and it was this break in the tubbing and consequent flooding of the mine that had to be dealt with by cementation.

Fig. 1 shows a section of the shaft, giving particulars of the shaft lining, ground, and position where the tubbing was blown out by explosion, the lower charge having been exploded previously without any very serious result. Fig. 2 is a plan of the cementation holes, each hole having been bored vertically downward to a depth of 125 yards, to ensure its reaching below the bottom of the water-bearing measures. The diameter

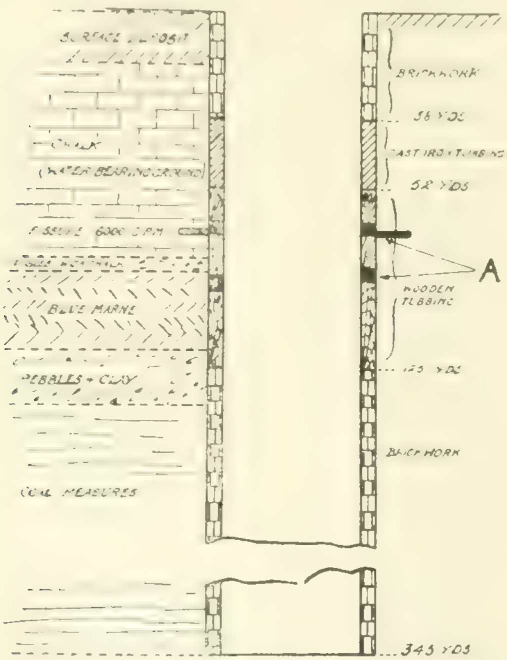

FIG. 1. SECTION OF A SHAFT, SHOWING TUBBING DESTROYED BY EXPLOSION.

High Water Mark of Permanent Chalk Water Level 45 yds. Low Water Mark 52 yds.; Tubbing broken by Explosion of Two 220 lb. charges shown at A.

of the shaft was 16 ft., that of the outside circle of holes 84 ft., and the inside circle 67 ft. The outside circle was injected and finished before the inside one was commenced. The holes were treated in pairs, being situated on opposite sides of the shaft, the one being bored while the other was being injected. An average of fourteen injections was found necessary in each hole, the injection commencing at a depth of 39 yards and being repeated about every 5 yards down, whenever water was being made in the hole. A total of 340 tons of cement was used for the outer holes and 101 tons for the inner ones. When injecting, the pressure was not allowed to rise above 200 lb. per square inch, this being found ample for the type of ground under treatment. One foreman and eleven men were employed on each shift, the total time taken for the completion of the work being just under three months. The following particulars of cement injected are interesting, as on referring to Fig. 2 they show clearly the amount of cement taken up by the fissure:

Hole	Cement injected Tons.	Hole	Cement injected, Tons.	Hole	Cement injected Tons.
1	56	9	30	17	14½
2	51	10	34	18	8
3	19	11	8	19	5
4	19½	12	17½	20	10
5	18	13	6½	21	8
6	41	14	4	22	2½
7	40	15	8	23	½
8	33	16	20	24	1½

On the water-level in the pit falling sufficiently to allow of the tubbing break being examined it was found that the flow of water had been completely sealed off, and in the place of the 6,000 gallons per minute feeder which was visible in the shaft on its previous examination three and a half years before, there was now only a small feeder of 25 gallons per minute, this latter being entirely sealed off after a few hours' further injection.

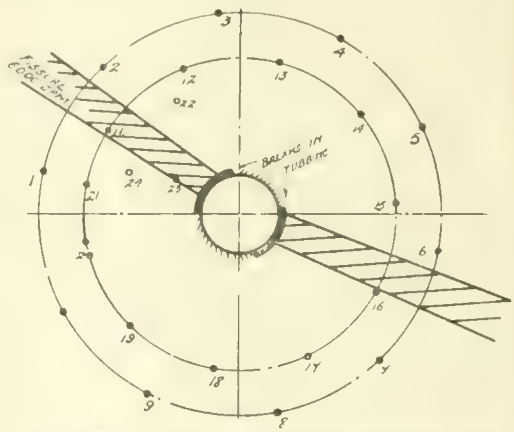

FIG. 2. PLAN OF CEMENTATION HOLES FOR THE REPAIRING OF TUBBING DESTROYED BY EXPLOSION.

Diameter of Shaft 16 ft.; Diameter of Outside Ring of Holes 84 ft.; Diameter of Inside Ring of Holes 68 ft.; Depth of Holes 360 ft.; Depth of Break in Tubbing 190 ft.

The successful treatment of the pit is one worthy of record, for with the exception of the fact that it was known that the tubbing had been badly broken at a vitally important part and that the shaft and neighbouring pits were completely flooded to a few yards from the surface, no information was available that was of any assistance in the preparation of the scheme of treatment. The majority of the pits were damaged by the Germans towards the end of 1915, and in consequence it had been found that at times the wooden tubbing had suffered considerably. In such cases the affected parts were treated by injection from the inside of the shaft. As a result of the cementation of pit No. 11 and other pits in the neighbourhood it was possible to start pumping operations on a large scale.

Chemistry of the Earth's Crust.—The *Journal* of the Franklin Institute for December contains an article with this title written by Henry S. Washington, petrologist of the petrological laboratory at the Carnegie Institution, Washington. After brief consideration of the interior of the earth, the general characters of igneous rocks are discussed, and the presence of water

vapour and other gases in the magma, and its analogy with a salt solution, are pointed out. In the discussion of the mineral characters of rocks, stress is laid on the fact that the number of essential rock-forming minerals is very small. These are mostly silicates of Al, Fe, Mg, Ca, Na, and K. Any two or more of these minerals (with two exceptions) may occur together and in any proportions. The chemical characters of igneous rocks are summarized, and the ranges and maxima of the various constituents are given. The average igneous rock is considered and, after some discussion of the sources of error involved in the calculation, a new average in terms of oxides (based on 5,179 analyses) is given. The average rock is shown to be approximately a granodiorite. The average composition of the earth's crust in terms of elements is also given. Twelve elements (O, Si, Al, Fe, Ca, Na, K, Mg, Ti, H, P, and Mn) make up 99·61% of the crust. The elements are referred to two main groups in the periodic table: (1) The petrogenic elements, characteristic of, and most abundant in, the igneous rocks, of low atomic weight, and occurring normally as oxides, silicates, chlorides, and fluorides; (2) the metallogenic elements, rare or absent in igneous rocks, but occurring as ores, of high atomic weight, and forming in nature native metals, sulphides, arsenides, bromides, etc., but not primarily oxides or silicates. The suggestion is made that beneath the silicate crust of petrogenic elements is a zone essentially of nickel-iron, and beneath this a central core of the metallogenic elements. This vertical distribution is in accord with Abbot's view as to the distribution of the elements in the sun. In igneous rocks and minerals the elements show a correlation, in that certain of them are prone to occur with others, and a similar limited correlation is apparently true of the animal and vegetable kingdoms. The idea of "comagmatic regions," that is, the distribution of igneous rocks in regions of chemically related magmas, is discussed, and some of these are briefly described. The calculation of rock densities from their chemical composition is discussed, and the average chemical compositions and densities of the continental masses and oceanic floors are given. It is shown by these that the average densities of the continents, ocean floors, and various smaller regions of the earth stand in inverse relation to their elevations. The bearing of this relation of average density and elevation on the theory of isostasy is pointed out, and it is shown that the data presented are confirmative of the theory.

Nickel and its Uses.—In *Chemical and Metallurgical Engineering* for January 5, Paul D Merica commences a series of articles on nickel and its alloys. We quote herewith his notes on commercial nickel and its uses.

Nickel appears on the market in the following forms:

(*a*) Grains, cubes, rondelles, or powder, reduced at a low temperature from nickel oxide and not fused in the process of manufacture.

(*b*) Nickel deposited in concentric layers from nickel carbonyl and not fused in the process of manufacture.

(*c*) Nickel deposited electrolytically in the form of cathode sheets.

(*d*) Nickel in the form of blocks or shots made by reducing nickel oxide above the melting point of nickel and casting the resulting molten metal or pouring it into water.

(*e*) Malleable nickel made in the same manner as (*d*) but treated with some deoxidizer before pouring into ingots. This nickel appears in the usual commercial forms, rods, sheets, wire, etc.

Most of the commercial production of nickel falls in class (*d*).

The International Nickel Co. has described the grades of material which it produces and contributes the average analyses of the materials given in the following table.

	Percentage Ni and Co.
1. Malleable Nickel Rods, A	99·00
2. " " " B	98·75
3. " " " C	96·75
4. Nickel Castings	98·95
5. Orford Electrolytic Nickel	99·84
6. Nickel Shot A	98·65
7. Nickel Shot X	99·05

The impurities were as follows: In (1) 0·55 Fe, 0·025 S, 0·10 Si, 0·15 C; and 0·15 Mn. In (2) 0·50 Fe, 0·025 S, 0·20 Si, 0·15 C, 1·75 Mn. In (3) 0·75 Fe, 0·03 S, 0·20 Si, 0·15 C, 1·75 Mn. In (4) 0·50 Fe, 0·035 S, 0·16 C. In (5) 0·01 Cu, 0·005 S, 0·005 C, 0·01 As, 0·01 Sn and Sb. In (6) 0·15 Cu, 0·80 Co, 0·50 Fe, 0·06 S, 0·15 Si, 0·45 C, 0·015 As, 0·015 Sn and Sb. In (7) 0·15 Cu 0·80 Co, 0·47 Fe, 0·04 S, 0·10 Si, 0·18 C, 0·015 As, 0·015 Sn and Sb.

"A" shot nickel is a high-carbon nickel used by manufacturers of anodes for nickel plating. "X" shot nickel is a purer material used by the manufacturers of crucible nickel steel and of nickel silver. Ingot or block nickel is almost identical in composition with "X" shot. It is sold in 25 lb. and 50 lb. blocks or ingots and is used in the manufacture of open-hearth and electric steel. Electrolytic nickel in the form of cathodes 24 by 36 in., weighing about 100 lb., or in smaller squares, and is used in the manufacture of high-grade nickel silver and cupro-nickel alloys. Malleable nickel intended for rolling into sheets or rods or for drawing into wire is made in various grades according to the purpose for which it is destined. All malleable nickel is treated before casting into ingots with some deoxidizer, generally magnesium, for the purpose of removing the nickel oxide present and making the metal suitable for rolling or forging. Manganese is also added both for the purpose of cleaning the metal and as an alloying element. Nickel cannot in general be rolled or forged without this preliminary treatment with a deoxidizer. Grades A and C malleable nickel ingots are used for rolling into rods and sheets and drawing into wire. There is also a grade D malleable nickel, which is high-manganese nickel having practically the same analysis as grade C, except that manganese varies from 2 to 5%. This is used principally for spark-plug wire to resist the action of high temperatures and combustion gases.

Besides these commercial forms of nickel, the metal is on the market in the form of anodes for the metal-plating industry. These cast anodes are variable in composition and contain from 88 to 95% nickel, together with iron, aluminium, tin, silicon, sulphur, and carbon. A typical analysis of a commercial anode is the following: graphitic carbon 1·70%, silicon 0·50%, iron 0·80%, copper 0·15%, aluminium 0·03%, nickel 96·82%.

The principal commercial application of nickel is in the manufacture of nickel steel, and this industry absorbed fully 75% of the total nickel production during the war and probably 65% normally. Besides its use in steel, nickel is used extensively as an alloying element with non-ferrous metals, principally copper. About 15% of the production is utilized in the manufacture of alloys of nickel, such as cupro nickel and nickel silver, the former series of alloys having come into prominence during the war. Nickel coinage and the electroplating industries may each absorb from 3 to 5% of the production, the latter requiring the metal both in the metallic form and in the form of nickel salts, the sulphate and double ammonium sulphate. The production of malleable nickel, although never relatively large, has amounted to about 5% of the total production, and is steadily growing in volume as the properties of the metal in this form become better known. Malleable

nickel is produced in all commercial forms and is used principally for coinage, cooking utensils (chiefly in Germany and Austria) and ornamental and household stampings and fittings. In the form of wire it is much used for motor-ignition spark-plug points, for the suspension wires in electric light bulbs, for electrical resistance pyrometers, electrical instruments, and recently in the construction of the audion amplifier. Some malleable nickel is produced in the form of castings for apparatus such as digesters and evaporators for the chemical industry, for which its resistance to corrosion in sulphuric and other acids makes it particularly suitable. The Edison storage cell contains nickel both in the form of nickel oxide and as nickel anodes. Finely divided nickel is much used as a catalytic agent in the hydrogenation or hardening of oils, following the discovery of this property by Sabatier and Senderens. Nickel oxide is used in the ceramic industries for the production of under or holding coats of enamel on steel, and also for colouring glazes on pottery. Nickel castings have been used with much success as rabble shoes by the International Nickel Co., in calcining furnaces used in roasting nickel matte. The shoes are exposed to oxidizing and to sulphurizing gases at temperature from 600 to 1,000° C. and to severe mechanical abrasion; they have stood up in this severe service for nine months, whereas iron shoes would last no more than from six to eight weeks.

Mica in Australia.—In the *Queensland Government Mining Journal* for October, B. Dunstan, Chief Government Geologist, gives an account of the mica production of the world. We extract the portion dealing with Australian occurrences.

Pegmatite veins containing large crystals of mica are known to occur on many of the mining fields of Northern Queensland, the deposits on the Einasleigh River to the south-east of Georgetown and at Brookland near Junction Creek, both within the Etheridge goldfield, being specially worthy of note. Attention has been directed to the occurrence of deposits in the Cloncurry district, and from recent examinations they appear to be of more importance than anything previously known in the State. They are situated on Rifle Creek, a tributary of the Upper (West) Leichhardt River, on Parkside No. 6 Pastoral Lease, and about 68 miles almost due west of the town of Cloncurry. Many references are given in the Queensland Mineral Index to mica occurrences, but without any information regarding their extent or value. As regards other occurrences in Australia, in the Northern Territory a mica mine was opened and abandoned some years ago at Hart's Range, to the north of Arltunga goldfield; in 1914 operations were again started, the war, however, stopping the work at the mine in consequence of the mica being intended for Germany. In South Australia it is reported to occur in an area near Williamstown, in the hundred of Barossa, and a low-grade deposit has been opened near the Warren Reservoir in the hundred of Para Wirra.

The country about the Rifle Creek mica area near Cloncurry is said to be in hornblendic and micaceous schist, in which a dyke of pegmatite was discovered to be made up almost exclusively of large crystals of mica, the thickness of the dyke being from 10 to 12 ft. A large number of pegmatite dykes, some with quartz predominating, occur in the locality, but have not been examined, although the mica-bearing belt is said to extend for several miles. Samples for examination have been received from the outcrops of these deposits, but no [illegible]s to have been made to determine the [illegible]ality of the mica below the surface [illegible] much stained with iron oxides, and [illegible]ry defective condition, as might be expected, but no doubt any blemishes in this surface material would disappear if the mica were obtained in deeper ground. Some of the crystals have well-developed cleavages, are roughly 9 in. square, and after being stripped and trimmed, even in their weathered condition, have given very satisfactory tests, electrical and otherwise. The deposits near Arltunga are in mica schist in the form of large pegmatite dykes of felspar, quartz, and mica. Some of the mica crystals obtained were several feet in diameter, and one specimen is said to have yielded 7 cwt. of trimmed mica sheets.

The question for consideration so far as Queensland is concerned is whether the Rifle Creek deposits contain mica equal in quality to that imported from America and India, and if so whether mining and dressing operations could be carried on cheaply enough to allow of competition with this imported material. Imperial demands for mica in connection with electrical and wireless work have stimulated the interest in these deposits and should induce miners to open up the outcrops, and obtain some estimate of the value of the very large mica sheets at a depth where they are not affected by weathering agencies. The distance from Rifle Creek to Cloncurry is 68 miles by road, and from Cloncurry to Townsville by rail 481 miles, altogether making 549 miles over which the product would have to be carried. In the mineral belt of country extending for many miles to the north-west and south-east of Cloncurry, and embracing the Rifle Creek deposits to the west, there is a large number of outcrops of granite and schist which all appear to be the result of the alteration of the associated sedimentary rocks. This area contains pegmatite dykes in the granites and schists which have never been prospected and the conditions are ideal for the occurrence of mica in qualities and sizes suitable for manufacturing purposes.

Vanadium in the Transvaal.—In the September issue reference was made to a company called the African Vanadium and Lead Co., formed in the Transvaal for the purpose of working lead-vanadium deposits at old Doornhoek lead mine, 17 miles south-east of Zeerust. The November issue of the *South African Journal of Industries* publishes the report made by Malcolm Ferguson, Inspector of Mines, Krugersdorp, and Dr. P. A. Wagner, Government Geologist. This report is reproduced herewith.

The deposit occurs in the upper portion of the dolomite formation. It consists of soft decomposed bedded manganese earth containing thin layers of chert and large masses and boulders of unaltered dolomite. Galena is scattered through the manganese earth in irregular nodules ranging in diameter from a fraction of an inch to over 2 ft. The nodules are often covered with a thin film of brilliant red minium, and some of them show traces of the original bedding of the dolomite. In addition, cerussite, vanadinite, and pyromorphite are present. These minerals occur in irregular layers following the bedding of the manganese earth, also in pockets, and finally encrusting vertical and steeply-inclined joint-planes. In the eastern part of the workings there is a big exposure of dolomite containing irregular masses and patches of galena, which has clearly developed by the replacement of the dolomite. It is associated with fluor-spar and talc. Whether this dolomite forms part of a great horse in the manganese earth, or whether it represents a projecting portion of the wall of the deposit, is not clear.

The deposit clearly owes its origin to a long and complex succession of metasomatic processes. In the first place galena appears to have been introduced from a series of inclined fractures striking N.E.-S.W. by mineralizing solutions that spread along the bedding planes

of the dolomite. The alteration of that rock to manganese earth took place subsequently, in all probability through the agency of descending meteoric waters. The formation of the vanadinite appears to have been connected with the conversion of the dolomite into manganese earth, but the evidence on the point is not quite conclusive.

The mine is situated on the east side of a valley, and has been opened by quarrying into the side of the hill, and up to the present the work has consisted mainly in turning over the quarried earth and extracting by hand the galena lumps which are sufficiently large to be picked out. Additional amounts of galena have been recovered from shafts sunk from the surface outside the quarry and from drives driven off the shafts and pushed in from the faces of the quarry. The eastern face of the quarry against the hillside is about 100 ft. high. The walls of the quarry practically everywhere appear to carry lead minerals. The mineral-bearing deposit is found to continue in the floor of the quarry and in the shaft and underground workings beyond, so that it is at present impossible to estimate the probable extent of the deposit. A rough traverse by prismatic compass was made of the most westerly underground workings at the 60 ft. level, and some samples were taken for analysis. Further samples were taken at various parts of the face of the quarry, and one from the dump. In the underground workings above referred to, and at the lower portion of the western face of the quarry, lead and vanadium ores were found to occur in fairly consistent quantities throughout the deposit over a considerable area and thickness. These workings cannot be looked upon as having opened up any tonnage of ore reserves. They merely serve to prove that the deposit exists over an extended area and carries the minerals referred to beyond the horizon of the present workings. The samples taken on the face of the quarry show the consistent nature of the lead contents throughout the deposit. The writers are of opinion that a considerable deposit carrying lead and vanadium ores exists, but that the extent of it cannot be determined at present.

Dr. James Moir, Government Mining Chemist, reports as follows on seven specimens of ore from the Doornhoek mine:

	Lead.	Vanadium Pentoxide.
	%	%
A.	9·95	0·90
B.	11·5	0·60
C.	8·15	0·45
D.	15·5	1·35
E.	14·3	0·40
F.	14·4	Uncertain trace.
G.	14·3	Trace about 0·2%.

Antimony Oxide as a Pigment.—At a meeting of the Oil & Colour Chemists' Association held last month, H. E. Clarke gave particulars of a new antimony oxide pigment put on the market under the name "Timonox." This pigment is said to be free from coarseness of crystalline structure and yellow impurity that have been the great drawbacks in the past. Two brands have been introduced, the "red star" being a very pure white colour, and the "green star" a pale ivory cast. The specific gravity of this antimony oxide is about 5·4, which is approximately that of zinc oxide. The two pigments, however, differ sharply in their behaviour with oil; antimony oxide is readily wetted, while its oil absorption is so much lower that good paste can be ground containing 10% of oil. It is said to be possible to prepare from such paste oil paints with as much as 78% pigment, which flow well under the brush and give coats of great opacity and purity of colour. For glossy finishes good results are obtained with about 10% le pigment. The drying rate is carefully adjusted, as there would seem to be a tendency to flatting when the drying is unduly delayed. Matt and semi-glossy effects are readily obtained. Antimony oxide has been found to have no accelerating effect on the drying of linseed oil, but this deficiency can be overcome by the incorporation of a small proportion of drier. This may take the form of litharge, white lead, manganese borate, zinc oxide, gold size, or a drying resinate or linoleate. These mixtures, however, require to be broken with rather more oil and less volatile thinner than white lead pastes. Durability and colour stability tests have shown that this pigment has excellent wearing properties. The films show practically no cracking and very little chalking. Zinc oxide has proved itself a useful auxiliary to antimony oxide, acting first as a drier and later as a hardener of the film.

Geology of Killifreth Mine.—At a meeting of the Royal Geological Society of Cornwall, held in November, M. H. Kitto read a paper describing the geology of Killifreth mine, near Redruth, with special reference to the middle lode. The mine is situated in the clay-slate a mile and a half north of the granite outcrop, but granite is met with in the 70 fathom level in the form of a tongue or apophysis, and again as a tongue in the 20 fathom level, where it is seen to pass into schorl rock. Quartz-porphyry dykes are met with at the 50 fathom level and again in the 40 fathom level. The middle lode has yielded blende, cassiterite, chalcopyrite, mispickel, molybdenite, pyrite, and wolfram, while smaltite has been found in a cross-course. The mineral values are irregularly distributed. The lode shows comb structure and in places is filled with cassiterite in tourmalinized slate, clean quartz with wolfram, clean quartz with wolfram and molybdenite in separate layers The author comes to the conclusion that there has been chiefly lateral movement with little or no vertical displacement in the cross-course which cuts the middle lode.

Geology of Carn Marth.—At a meeting of the Royal Geological Society of Cornwall, held in November, G. M. McPherson, Jr., read a paper on the geology of Carn Marth, and of the district lying immediately to the east of Redruth. He describes some interesting cases of differentiation in the granite and concludes that four types of rock are represented: (1) the original coarse muscovite biotite granite which forms the bulk of the mass; (2) an intrusion of fine-grained granite which penetrated the coarse type with an irregular line of contact along which it is seen to contain coarse crystals of felspar; (3) an intrusion of fine-grained schorl granite which penetrates the fine granite but does not reach the coarse type; (4) an intrusion of pegmatite, and in the coarse granite only narrow dykes of aplite. The author also describes a contact of two quartz-porphyry dykes (elvans) which occurs at the junction of the granite and clay-slate.

SHORT NOTICES.

Mine Signalling.—The *Colliery Guardian* for January 7 describes the Granville audible and visual signalling apparatus, as applied at the Granville colliery, Burton-on-Trent.

Ventilation in Mines.—The November *Journal* of the Chemical, Metallurgical, & Mining Society of South Africa contains an article by E. J. Laschinger describing ventilation tests at Village Deep undertaken with the object of ascertaining the amount of fresh air required to remove the fumes after blasting in development drives.

Kata-thermometer. In a paper published in the November *Journal* of the Chemical, Metallurgical, & Mining Society of South Africa, H. J. Ireland describes Dr. Leonard Hill's kata-thermometer, which is used for measuring the cooling power of the atmosphere.

Copper Smelting in Japan. In the *Engineering and Mining Journal* for January 8, C. F. Mason describes the operation of the Hidachi copper smelter in Japan.

Bunker Hill.—In the *Mining and Scientific Press* for January 8, T. A. Rickard describes the Bunker Hill & Sullivan Company's lead-smelting plant.

Cadmium. *Chemical and Metallurgical Engineering* for December 29 contains a paper by H. R. Hanley on an electrolytic process for producing cadmium as devised by the author at the Mammoth electrolytic zinc plant of the United States Smelting, Refining, & Mining Co., at Kennett, California.

Cyaniding. — In the *Engineering and Mining Journal* for January 15 and 22, Alfred James reviews the position of the cyanide process.

American Sulphur.—*Chemical and Metallurgical Engineering* for January 12 reprints a paper read by R. F. Bacon and H. S. Davis before the American Institute of Chemical Engineers on December 6, describing the American resources of elemental sulphur, particularly those in Texas, and comparing the relative advantages of pyrites and sulphur as a source of sulphuric acid.

Midland Coalfields.—A paper was read by H. H. Ridsdale at the January meeting of the South Staffordshire and Warwickshire Institute of Mining Engineers on the geological relationship of the South Staffordshire, Warwickshire, South Derbyshire, and Leicestershire coalfields.

Oil in India.—The *Geological Magazine* for January contains a paper on the geology of the oil regions in the northern Punjab, India, by H. Preiswerk.

Old Sussex Iron Industry. — At the meeting of the Newcomen Society, held on January 27, Rhys Jenkins read a paper on the rise and fall of the iron manufacture in Sussex.

World's Copper Production.—In the *Geological Magazine* for January, Dr. F. H. Hatch writes on the growth of the world's copper production.

Low-Temperature Carbonization.—At a meeting of the Society of Chemical Industry held on January 3, G. H. Thurston read a paper describing the Smith low-temperature system of carbonization.

Building Stones.—At the meeting of the Concrete Institute held on January 27, J. Allen Howe read a paper on geology in relation to building stones.

Cementation at the Mazoe Dam.—In a paper published in the November *Journal* of the Chemical, Metallurgical, & Mining Society of South Africa, G. A. Voskule described the hardening of the substrata of the Mazoe dam in Rhodesia, effected by means of the Francois cementation process.

Trestle Viaducts.—The *Engineer* for January 21 gives particulars and drawings of the old timber viaducts on the Great Western Railway in Cornwall and Devon. These bridges were built in Brunel's days, but have gradually been replaced by stone viaducts. At present two are being removed on the Kingswear branch and two of the eight on the Falmouth branch are to be removed shortly.

Arthur De Wint Foote.—The *Mining and Scientific Press* for December 25 contains the report of an interview between Mr. Foote and Mr. T. A. Rickard giving the former's record. Mr. Foote's work at the North Star gold mine, in Grass Valley, California, is of great interest to mining engineers.

RECENT PATENTS PUBLISHED.

☞ *A copy of the specification of any of the patents mentioned in this column can be obtained by sending 1s. to the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. 2, with a note of the number and year of the patent.*

14,865 of 1917 (155,600). C. J. HEAD, London. Production of tungsten powder by heating sodium with sal ammoniac and carbon.

4,376 of 1919 (155,855). A. R. MANGNALL, Chester. Boring machine for forcing a heading through soft ground.

11,184-6 of 1919 (126,625-7). P. DESACHY, Paris. Method of preparing an anhydrous zinc sulphide from hydrated sulphide precipitated from solutions by chemical reactions.

19,316 of 1919 (142,432). C. P. MADSEN, Newark, New Jersey. Improved method of electrolytic plating with nickel.

20,891 of 1919 (125,875). W. BROADBRIDGE, E. EDSER, W. W. STENNING, and MINERALS SEPARATION, LTD., London. In the separation of coal from stone by the agitation-froth method the use of a flocculating medium which will serve as a binding agent in the production of briquettes.

22,174 of 1919 (137,273). BROWN, BOVERI & Co., Baden, Switzerland. In air-compressors of the rotary type, methods of preventing the surging of the delivery.

22,370 of 1919 (155,349). L. A. WOOD and MINERALS SEPARATION, LTD., London. In the agitation-froth concentration process, in which air is introduced below the agitator, the arrangement of a grid just above the agitator.

22,825 of 1919 (155,373). H. T. ARROWSMITH, Burslem. Method of making acid pots used in the manufacture of white lead.

23,352 of 1919 (155,644). G. HENZE and E. WEBER, Brussels. An internal combustion engine suitable for use on mine locomotives.

25,545 of 1919 (155,945). P. A. MACKAY, London. Method of making sulphate of lead from metallic lead by the attack of strong sulphuric acid.

26,231 and 28,489 of 1919 (155,692). J. J. HOOD, London. Method of purifying sulphur.

26,310 of 1919 (155,953). G. BECKER, Magdeburg, Germany. Improvements in conveyors of the jigging type.

27,784 of 1919 (135,186). AKTIEBOLAGET FERROLEGERINGAR, Stockholm. Method of preparing manganese and manganese alloys low in carbon and silicon.

27,785 of 1919 (135,187). AKTIEBOLAGET FERROLEGERINGAR, Stockholm. Method of removing silicon and carbon from chromium and chromium alloys.

1,715 of 1920 (138,083). W. FRIEDERICK, Cologne. Detonating caps, loaded with a suitable nitro compound, primed with an initial charge of lead azide, and lead tri-nitro-resorcinate placed over it.

3,279 of 1920 (139,160). B. RAEDER and A. S. ZINK CO., Christiania, Norway. Arrangement of drying, heating, and reduction chambers in electric furnaces for producing zinc.

3,892 of 1920 (155,145). G. H. ELMORE and H. L. MCLEAN, Scranton, Pennsylvania. Jigs for coal washing.

4,369 of 1920 (138,924). NEW JERSEY ZINC CO., F. G. BREYER, and E. H. BUNCE, New York. Method of treating impure zinc oxides by heat for the improvement of their colour and their suitability for use as pigments.

5,532 of 1920 (156,019). J. DEAN, Racine, Wisconsin. Mechanical method of preparing the surface of aluminium to permit of coating, tinning, or soldering.

6,049 of 1920 (139,520). SOCIÉTÉ ANONYME DES CHARBONNAGES DE BEERINGEN, Liége. Improvements in the method of shaft-sinking by means of freezing.

9,633 of 1920 (155,739). METAL & THERMIT CORPORATION, New York. Method of introducing tungsten metal into molten steel for the formation of tungsten steel.

15,884 of 1920 (144,728). FRIED KRUPP GRUSONWERK, Magdeburg-Buckau, Germany. Improvements in the chloridizing-roasting process, particularly with the object of separating lead and silver from complex zinc-lead ores.

16,162 of 1920 (145,047). SIEMENS-SCHUCKERTWERKE, Berlin. Improved transporter for use in connection with tunnelling and mining machines.

16,559 of 1920 (146,108). R. M. MCKENNA, Washington, U.S.A. Purification of ferro-tungsten, by treating with hydrochloric acid for the removal of sulphur, carbon, and phosphorus.

17,690 of 1920 (155,522). L. A. IRAZUSTA, Guipuzcoa, Spain. Use of pure alumina and water as binding agent for fine iron ores, in the manufacture of briquettes for smelting

17,760 of 1920 (145,600). P. GOLDBERG, Berlin. Electrolytic process for separating copper and nickel.

24,854 of 1920 (151,260). G. HAGLUND, Falun, Sweden. Improved electrolytic cell for the deposition of nickel from solutions.

NEW BOOKS, PAMPHLETS, Etc.

☛ Copies of the books, etc., mentioned below can be obtained through the Technical Bookshop of *The Mining Magazine*, 724, Salisbury House, London Wall, E.C.2.

Coal; being one of the Monographs on Mineral Resources with Special Reference to the British Empire, issued by the Imperial Institute. By J. H. RONALDSON, M.Inst M.E., M.Inst.M.M., F.G.S. Paper covers, octavo, 166 pages. Price 6s. net. London: John Murray.

In this little volume Mr. Ronaldson has attempted the almost impossible task of producing an account of the coal resources of the entire British Empire. To do this adequately, many such volumes and at least as many authors would be needed; no one man can possess all the requisite information, and no one book can contain it. Mr. Ronaldson's book is of course only a compilation of matter already published, but it can fairly claim to present in a convenient form a sketch of the coalfields of the British Empire and to act as an index to the vast mass of scattered publications on the subject. The author has of course drawn mainly upon the great work, "The Coal Resources of the World," published in 1913 in Canada under the auspices of the International Geological Congress, and most of the statistics given are quoted from this. Unfortunately the author has drawn some of his statistical matter somewhat indiscriminately from other sources, as, for example, for Great Britain from the Report of the 1904 Commission on Coal Supplies or from Hull's work on the Coalfields of Great Britain, and uses at times the figures from one source, at times from another, and even in places puts down two sets of estimates and leaves it to the reader to select whichever he may happen to fancy. The same want of care in the due co-ordination of his sources of information may be seen in such an example as in the spelling of the same coalfield as "Jharia" and "Jherria" respectively on two adjoining pages. The portion of the book that will probably strike the reader as the least satisfactory is that relating to the coalfields of Great Britain, though this may be merely due to the fact that information concerning these is better known and more readily accessible. It is noteworthy that Mr. Ronaldson has given only 15 references to literature concerning the United Kingdom, and has omitted some of the most important; thus he would no doubt have written differently from what he has done had he consulted Stanley Smith's work on the Limestone Coals of the Northumberland coalfield, while again he seems to have made no use of A. E. Ritchie's book on the Kent coalfield. It is at least as surprising that he has not availed himself of the mass of valuable matter to be found in the Transactions of the Institution of Mining Engineers. In spite, however, of such imperfections and limitations, the book should be found decidedly useful to a wide circle of readers, particularly if care is taken to consult on all matters of detail the more extensive works, of which the present volume may be regarded in the light of a convenient abstract.

HENRY LOUIS.

The Platinum Metals. By A. D. LUMB, A.R S.M., F.G.S., Assoc.Inst.M.M. Octavo, paper covers, 63 pages. Price 3s. 6d. net. London: John Murray.

This book is one of the monographs on mineral resources with special reference to the British Empire, prepared under the direction of the Imperial Institute. The 63 pages are divided into three chapters. Chapter I deals with the occurrences, characters, and uses of the platinum metals, and contains interesting tables giving various analyses of platinum from different parts of the world, a list of the principal platinum and palladium alloys, the world's output of platinum from 1910 to 1918, and others. As regards the world's output of platinum, the author on page 13 mentions that "it appears to have been a tendency for private enterprises (in Russia) to keep these published outputs as low as possible in order to avoid registration." In this respect the author is wrongly informed, and such a serious statement should certainly never have been made without closer investigation. The real discrepancy between official and actual figures is solely due to theft either by workmen from their employers or by marauders working without licence or authority. Chapter II, which deals with the sources of supply of the platinum metals from the British Empire, contains in condensed form descriptions of occurrences throughout the Empire. It is very complete and useful. Chapter III is devoted to the supply of platinum metals from foreign countries. It lacks accuracy; the geological data for some of the countries are decidedly antiquated and a good many mis-spellings (or are they printer's errors?) should have been avoided. In France there is no Department of "Charaste," but "Charente"; "Chatelard" is given as "Chatalard"; in French Guiana the river "Aporuague" should be "Apronaguel" and "Danmer" should be "Damour." The platinum deposits in Germany, according to the author, are quite real and practically ready to start exploitation. Yet Krusch, the author cited, entitles his treatise on these deposits: "Die *Platinverdächtigen* Lagerstätten etc," that is, the deposits *suspected* of containing platinum, etc. Krusch cites assay-results made by one and the same method, on the same material but in different laboratories, thus:

	1st Laboratory Grammes per Ton.	2nd Laboratory Grammes per Ton.
No. 1	30 00	Traces
No. 2	35 05	3 8
No. 3	8 00	0 8

In the face of such facts, by simply saying that his

samples yielded values varying from a trace to 33.5 grammes per ton, a wrong impression is being conveyed. The German deposits from a technical point of view are far from being proved. As regards Russia, the statistical data are substantially correct, but the geography dealing with the deposits is not properly co-ordinated and rather confusing, even wrong. Describing the methods in use in certain parts of Russia when working the deposits in winter, the author states (page 40) that the deposits are allowed to freeze and the frozen ground is mined after having partially thawed. This method is, however, only resorted to for prospecting purposes, as has been extensively described in Leon Perret's paper in Volume xxi. of the Transactions of the Institution of Mining and Metallurgy. The references to literature on the platinum metals, while extensive in many instances, are second-hand; besides, they are not sufficiently up to date. A publication by Visotski is mentioned which dates back to 1903 and which in the original is entitled "*Preliminary* Notice on the Platinum Deposits, etc." His completed treatise was published in 1913 and bears the title "The Alluvial Platinum Deposits of the Iss and of Nijny Taguil in the Urals." The latter publication should have been consulted. Some of the eminent workers on the geology of platinum deposits are not mentioned at all, for instance, Feodoroff, Nikitin, Levinson-Lessing, etc. The book under review is framed on a comprehensive basis and deserves re-editing. Its shortcomings could readily be amended; they should certainly not have escaped the vigilance of the scientific and technical staff of the Imperial Institute.

A. L. SIMON.

Geology of the Non-Metallic Mineral Deposits other than Silicates. Volume I. Principles of Salt Deposition. By AMADEUS W. GRABAU. Cloth, octavo, 430 pages, illustrated. Price 30s. New York and London: The McGraw-Hill Book Co.

Those who have carefully studied the author's "Principles of Stratigraphy" will welcome the appearance of the present volume, which deals in a most lucid manner with the practical application of those principles in so far as they affect salt deposition. In this term "salt" are included nitrates, phosphates, borates, common salt, and similar deposits, thus embracing a wide field of investigation, and the author has spared no pains to treat the subject as systematically and originally as he expounded his theories of stratigraphical geology in his former standard work, though with this exception: that a somewhat heavy style and cumbersome nomenclature characteristic of the "Principles" find no place in this later production, to its very distinct advantage.

As in so many phases of applied stratigraphy, our knowledge of the geology of salt deposits has its decided limitations, and even the standard textbooks are astonishingly vague or stereotyped in their treatment of the matter; certain well-defined theories of salt deposition (using the word salt in its more restricted sense), modelled on the lines of the famous Stassfurt occurrence, recur in nearly every publication on the subject with monotonous frequency, with little, if any, review or modification in the light of advancement of general ideas on stratigraphy. There is nothing vague or stereotyped in this book, and its advent anticipates and lays the foundation for a distinct line of progress to be followed in future researches of this branch of economic geology.

The author first considers the natural salts, their mineral characteristics and classification from a strictly chemical standpoint; this includes a valuable glossary of the principal properties and mode of occurrence of the non metallic salts (other than silicates), oxides, hydrocarbons, and non metallic native elements. This is followed by a very succinct account of Van 't Hoff's famous researches on oceanic deposition, illustrated by saturation and crystallization diagrams, in the chapter dealing with the sea as a source of saline deposits; in this chapter, Grabau's treatment of the biological factors involved is good, but we would have preferred a fuller discussion of the parts played by marine bacteria and algæ in the secretion of lime salts than he has given us, on the lines of Drew's excellent paper of 1914 (Carnegie Institute of Washington), to which the author makes only passing reference. Although he anticipates this criticism in the preface to a certain extent, it is doubtful whether a sudden flood of illustrations of modern and extinct organisms included at this stage makes up for the omission of details so essentially cognate to the subject. The succeeding four chapters are devoted to a consideration of the several phases of marine salt deposition, and include a short description of those interesting "cyclic salts," illustrated with reference to Holland and Christy's account of the well-known Sambhar Lake of Rajputana. This type of deposit is defined as salt which has been lifted from the sea with the spray, blown inland and deposited either near to the coastal margin, or under special circumstances (as at Sambhar) in inland drainage basins.

The next section deals with terrestrial salt deposition, and in our opinion is the most valuable part of the book; all deposits of this description are classified with reference to both the source of the material and the cause of deposition; with this as a basis, the reader is presented with a very able thesis on this phase of the subject. In particular chapters 9 and 10 deserve special mention; in the former he discusses "connate salts," a phrase happily chosen to define a type of inorganic sediment of which little account is usually taken by the average geo-physicist. Connate salt implies just that deposit derived from seawater and enclosed with the sediments actually laid down therein, and when not removed by subsequent leaching action, constitutes a fundamental factor in the formation of salt deposits, and one hitherto unappreciated at its full stratigraphical significance.

The succeeding pages are devoted to a consideration of nitrates, phosphates, and salts derived from hot springs, mineral springs, and the like, and in the penultimate chapter the author discusses several theories of origin of those curious salt-dome structures which are so imperfectly understood and at the same time of such far-reaching importance, particularly in oilfield technology.

We strongly recommend this volume to all those interested in problems of salt deposition and economics, and we look forward to the promised volume 2, and also to the volume on hydrocarbons at which the author hints in his preface.

H. B. MILNER.

Mineralogy. By Drs. E. H. KRAUS and W. F. HUNT Cloth, octavo, 580 pages, illustrated. Price 27s. net New York and London: The McGraw-Hill Book Co

The volume is described as an introduction to the study of minerals and crystals. In the introduction the authors point out the intimate connection between mineralogy and mining and agriculture, and hence also commerce and industry generally. Its relations to the other sciences is indicated, and its origin on a scientific basis is justly credited to Werner. The introduction is followed by chapters on crystallography, which are illustrated by photographs of actual crystals and crysta

models, in addition to line drawings. This should help the student, whose training in solid geometry is usually slight, to master the initial difficulties of the subject. Chapters dealing with the polarizing microscope and chemical properties of minerals follow, and the introductory matter is completed by chapters on the formation and occurrence of minerals and on qualitative blow-pipe methods. Descriptive mineralogy, including a chapter on gems and gem stones, occupies about 150 pages, followed by classification tables and a glossary of terms. The text is copiously illustrated by figures and photographs, and also by portraits of eminent mineralogists. The definitions of the terms "drusy" and "hydration" as given in the glossary might be improved, and it is to be noted that while the names of some plutonic rocks are given others are omitted. An inspection of the blow-pipe tests shows them to be complete and up-to-date, but it should be mentioned that some varieties of cassiterite refuse to yield a satisfactory result with the zinc and hydrochloric acid test. The book can be thoroughly recommended to the student as an introduction to the subject, and is especially suitable to one attempting to improve his knowledge of minerals without access to lectures and demonstrations.

E. H. DAVISON.

The Ore Deposits of Utah. By B. S. BUTLER, G. F. LOUGHLIN, V. C. HEIKES, and others. Professional Paper No. 111 of the United States Geological Survey.

A discussion of the numerous ore deposits of a State that has produced nearly a thousand million dollars worth of metals, and written by such a galaxy of eminent economic geologists as the experts of the United States Geological Survey, is a work of exceptional interest to mining geologists and engineers in general. Such is this volume. It contains accounts of copper, silver, gold, lead, and zinc deposits of great variety, besides descriptions of deposits of many other less common metals, together with critical discussions of the modes of genesis of the several kinds of deposits. While most of these deposits are derived from igneous sources, many occur in sedimentary formations often showing no obvious connection with igneous rocks and of doubtful affinities. Covering such a wide range of types the work is practically a textbook on ore deposits and their modes of genesis. It is profusely illustrated both with field photographs and photomicrographs illustrating important points in occurrence, and contains numerous statistical diagrams. Among features of special interest may be mentioned the descriptions of alunite veins and a critical discussion of the genesis of sulphuric acid under magmatic conditions and the general problems of primary sulphate veins. Alunite veins and alunitization are geological features that are particularly well developed in Utah. The volume also contains much information on the problems of metamorphism and some very interesting applications of quantitative methods for elucidating the probable characters of the solutions or emanations that have brought about metamorphic changes and the deposition of ore minerals. Altogether the work is one that may be studied with profit by all interested in the problems of ore occurrence and ore genesis.

W. H. GOODCHILD.

The Geology and Ore Deposits of Ely, Nevada. By ARTHUR C. SPENCER. Professional Paper 96 of the United States Geological Survey.

This volume is of great interest to the general student of ore deposits as a treatise on the occurrence and genesis of the huge disseminated copper or mineralized porphyry deposits that have contributed so largely to the establishment of America's pre-eminent position as the producer of such a large proportion of the world's copper supply. In addition to and apart from its local interest as a descriptive treatise on the ore deposits of a particular region, it is of special interest in that it gives a very full account of the processes of primary or igneous and secondary or katamorphic metamorphism, both of which processes have been necessary to generate rock sufficiently impregnated with metalliferous material to rank as commercial copper ore. The chemistry of secondary enrichment of lean primary iron and copper sulphides is discussed in considerable detail. The primary or igneous metamorphism and mineralization of the monzonitic porphyry intrusives, which carried little or no mineral as originally formed, is fully described, and the extensive changes wrought in the rock-masses are ascribed to magmatic waters emanating from an internal magma reservoir undergoing crystallization, the reservoir being the parent reservoir of the monzonitic extrusions. It is of interest and indeed somewhat striking that the theory of primary sulphide mineralization and wholesale metamorphism here quite independently put forward, as a result of careful and detailed geological surveying in this region, to account for the introduction of the enormous quantities of pyrite and accompanying copper, together with the accompanying silicate metamorphism, is identical in principle with the theory put forward elsewhere by the reviewer to account for the wholesale metamorphism of the Witwatersrand series and the introduction of iron sulphides and gold in large quantities into the conglomerates and their associated rocks. There seems to be a marked parallelism between the two types of occurrence, which, though differing considerably in detail, are closely allied in principle, so that it seems possible that a study of the copper porphyries of the New World might be helpful in the elucidation of the great gold problem of South Africa.

W. H. GOODCHILD.

Chemical Analyses of Igneous Rocks. By HENRY STEPHENS WASHINGTON. Professional Paper 99 of the United States Geological Survey.

This volume is a revised and greatly enlarged edition of the original tables of rock analyses collected by the same author, and published as Professional Paper 14 of the United States Geological Survey. This edition embraces the analyses of no less than 8,602 igneous rock samples as against 2,281 in the original paper. It is undoubtedly the most complete collection of igneous rock analyses extant and, having regard to the care with which it has been compiled, may be regarded as the standard work of reference on this important branch of petrological research. The tables give the analysis of each rock, together with its ordinary name, the locality from which the specimen was obtained, the name of the analyst, the bibliographical reference to the source of information, its position in the quantitative system, and remarks. To quote the author's words, "it is coming to be recognized by petrologists in general that the study of igneous rocks is in large part the study of silicate solutions and their equilibria, often complicated by the presence of volatile components, and is thus to be regarded as essentially a branch of physical chemistry." For such a study rock analyses are all-important and, indeed, indispensable. Hence the importance and value of this work to all geologists concerned with the study of igneous rocks, and, it may be added, to mining geologists in particular, since so many ore deposits are derived from such rocks or the molten masses from which they have crystallized. The tables are prefaced with a critical discussion of the character and use of such analyses and contain much in-

formation of value to geologists who may not be familiar with the chemical methods of rock analysis and the possible errors in ordinary rock analyses. The well-known quantitative system of classification is adopted in the presentation of the analysis. Whatever may be said as to the limitations and shortcomings of this system as at present developed, there can be no question as to the usefulness of this volume as a dictionary of igneous rock analyses. The construction of the system and a general explanation of its principles and practical working is given in an appendix, so that the work is complete in itself and can be used by those who may not be accustomed to its peculiar conventions and usages. The work is one that should find a place in the library of every petrologist and mining geologist.

W. H. GOODCHILD.

Wire Ropes for Hoisting. Quarto, 284 pages, with many illustrations. Price 20s. net. Johannesburg: The South African Institution of Engineers.

This volume contains a reprint of extracts from articles, etc., appearing in the publications of the South African Institution of Engineers and of the previously existing societies of which it is the successor. The papers and articles are not by any means given in full. In most cases parts of the discussion are given also. The following are the titles of the papers: Winding Plants for Great Depths, by Hans. C. Behr (1902); Rope Statistics, extracted from *Glückauf* (1903); Notes on the Corrosion of Wire Ropes by Mine Waters, by W. S. Thomas (1904); An Investigation Regarding the Effect of Kinetic Shocks on Winding Ropes in Vertical Shafts, by J. A. Vaughan (1904); The Risk Arising from Using Winding Ropes with too High an Initial Factor of Safety, by H. J. S. Heather (1905); Some Interesting Repairs to Machinery, by K. Schweder (1906); Wire Ropes Used for Winding: Their Strength and Some Causes for its Reduction, by J. A. Vaughan and W. M. Epton (1905); Some Notes on an Electrical Apparatus for Ascertaining the Cross Sectional Area of Wire Ropes, by C. McCann (1906); A Few Notes on Results of Tests of Worn Ropes, by W. M. Epton (1907); Record Keeping as Applied to the Resident Engineer's Department of a Mine, by H. L. Templer (1909); The Kimberley System of Handling Large Quantities of Ground in the Minimum of Time, with Notes Regarding the Life of Wire Ropes, by A. F. Williams (1911); Notes on the Margin of Safety Required by Government for Man Haulage at Great Depths, by R. B. Greer (1912); Hauling from Great Depths, by H. Kestner (1913); Notes on the Value of Annealing the Connecting Attachments on Winding Plants, by J. A. Vaughan (1916); The Factor of Safety of Wire Ropes Used for Winding in Mine Shafts, by J. A. Vaughan (1917).

Geology of the Northern Portions of the Districts of Marico and Rustenburg, Transvaal. By H. KYNASTON, W. A. HUMPHREY, and A. W. ROGERS. Pamphlet and maps published by the Geological Survey of South Africa.

Geology of Pondoland. By A. L. DU TOIT and A. W. ROGERS. Pamphlet and map published by the Geological Survey of South Africa. The copper-nickel deposits at Insizwa lie on the north-western border of the area covered by this work.

The Limestone Resources of the Union of South Africa II. By W. WYBERGH. Memoir No. 11 of the Geological Survey of South Africa, dealing with the limestones of Natal, the Cape, and Orange Free State.

Corundum in the Northern and Eastern Transvaal. By A. L. HALL. Memoir No. 15 of the Geological Survey of South Africa; 220 pages, with many maps and other illustrations. This volume gives detailed information as to the many corundum deposits of the Transvaal with an account of the geology of the country. A paper on this subject by Dr. P. A. Wagner was quoted in the MAGAZINE for September, 1918.

Asbestos 1913 to 1919. Pamphlet published by the Imperial Mineral Resources Bureau. Price 1s.

Manganese Deposits, Peak Hill Goldfield. By A. MONTGOMERY, State Mining Engineer for West Australia. This report describes manganese deposits at Horseshoe Range in the Peak Hill goldfield.

Geology of the Enterprise Mineral Belt. By H. B. MAUFE, Director of the Rhodesian Geological Survey. Geological Survey Bulletin No. 7.

COMPANY REPORTS

Wolhuter Gold Mines.—This company was formed in 1887 to work a gold-mining property on the outcrop on the central Rand. The control passed from the Neumann group a year or two ago to the Central Mining & Investment Corporation. The report for the year ended October 31 last shows that 396,292 tons of ore was raised, and, after the rejection of waste, 369,600 tons averaging 5·9 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 71,841 oz. and by cyaniding 31,828 oz., being a total of 103,669 oz. or 5·6 dwt. per ton. The par value of this gold was £435,337, but an additional income of £133,000, arising from the premium, was realized. The working cost was £433,001, or 23s. 5d. per ton, leaving a profit of £135,336. Dividends absorbing £107,500 were distributed, being at the rate of 12½%. The ore reserve is estimated at 661,904 tons averaging 5·7 dwt. The mine is fully developed and the number of available stope faces is gradually decreasing. In order to maintain the output it becomes necessary to draw from reclamation sources ore of lower grade. Thus in the future smaller profits will be made, and it will only be by means of the gold premium that the mine can be kept working.

Messina (Transvaal) Development.—This company was formed in 1905 to work copper properties in the northern Transvaal. Though the ore was rich it was not possible for some time to make profits owing to the high cost of shipment to England. Subsequently, when treatment plant was provided, the richer ore had become exhausted. The only dividends paid were for the years ended June 30, 1916, and June 30, 1917. The cessation of shipments of matte during the latter part of the war was another adverse factor. As already recorded, it was decided recently to build a new mill and a new smelter and refinery, the financing of which was provided by a subsidiary company called the Transvaal Smelting & Refining Co., Ltd., which would treat other ores as well. The report for the year ended June 30 last shows that 11,659 tons, averaging 5·1% copper, was raised from the Vogelenzang mine, and 80,488 tons, averaging 2·51%, from the Messina mine. The results of concentration were: 55 tons of picked shipping ore and concentrate, averaging 68%, and 5,871 tons of concentrate, averaging 33·4%, suitable for smelting on the spot. The matte produced by smelting 6,284 tons of ore and concentrate was 3,036 tons, averaging 63·6%. Concentration and smelting were suspended at the beginning of May, owing to the operations not being profitable, and the building of the new plant was commenced. Owing to the usual delays it is not expected that the new plant will be finished until April of this year. The accounts show an income of £174,089 from the sale of products, and the adverse

balance was £124,424. The proved ore reserve at the Vogelenzang mine is estimated at 28,370 tons, averaging 5·12%, and at the Messina 124,071 tons, averaging 3·84%. Taking into account the probable and possible ore, these figures become 85,202 tons, averaging 3·72%, and 433,508 tons, averaging 3·14%, respectively.

Tanganyika Concessions.—This company was formed in 1899 by Robert Williams to develop lands in northern Rhodesia. The Kansanshi copper-gold mine was opened, but is not now being worked. Subsequently a 40% interest in the Union Minière du Haut Katanga was acquired. This Belgian company operates copper and other mines in Congo State. The report of Tanganyika Concessions for the year ended June 30 last shows that the output of copper during 1919 was 23,004 tons, and that the output for 1920 is estimated at 19,000 tons. The output of tin concentrate at the Busanga tin mine to August 31 last was 272 tons. The present output is about 50 tons per month, and is expected shortly to be increased to 80 tons. Prospecting for tin has been conducted at several points in the Kasonso district with encouraging results. Coal deposits have been discovered by drilling close to the railway near Sankishia, and the evidence indicates the coal to be of considerable extent. Combustion tests show that the coal is useful for steam-raising but not for coke manufacture. The company is also largely interested in the Benguella railway, the Katanga Railway, and the Rhodesia-Katanga Railway. Recently a substantial interest has been taken in the Nile-Congo Divide Syndicate, which has been formed to investigate mineral deposits in the Sudan along the Nile-Congo watershed. The utilization of water power derived from falls on the Lualaba and Lufira rivers is still under consideration, the chief object being to secure cheap electricity on a large scale for the electrolytic treatment of low-grade copper ores. As already recorded, the debentures have been paid off by means of funds raised by the issue of a million new shares at £3 each. The company has taken its proportion of a new issue made by Union Minière, namely, 9,800 shares at 800 francs each. The accounts show the receipt of a dividend from the holding in Union Minière shares, 4,900,000 francs, which, at 56·5 francs to the pound, realized £86,725. Interest on loans and investments brought £45,918. The net profit was £89,666, which was carried forward.

Wankie Colliery.—This company was formed in 1899 to acquire coal lands in Rhodesia, north of Living-

stone Falls, about 200 miles north-west of Bulawayo. The railway from Bulawayo northwards, passing through the property, was opened in 1903. Edmund Davis is chairman and managing director, and A R Thomson is manager. The report for the year ended August 31 shows that the sales of coal were 320,476 tons and of coke 102,681 tons. The revenue for the year was £309,667, and the profit was £57,595, out of which £56,733 has been paid as dividend, being at the rate of 10%. The mine was idle for 54 days, due to strikes and shortage of truck supply. Nevertheless the output showed an increase of 17% on the previous year. A strike which lasted from December 22, 1919, to January 3, 1920, was not directed against the company, but was in sympathy with strikers at other mines. The supply of native labour has greatly improved. The developed reserve is estimated at 6,015,000 tons, and the probable reserve within a two-mile radius at 54,000,000 tons. As recorded a year or more ago, it is not convenient to extend operations at the present workings, so new workings are being opened at another site, where shaft-sinking is now in progress.

Premier (Transvaal) Diamond Mining.—This company was formed in 1902 to work diamond pipes north of Pretoria. Control was obtained by Barnato Brothers in 1912, and it was transferred to the De Beers company in 1917. The report for the year ended October 31 last shows that 4,660,498 loads (16 cu. ft. each) was washed for a yield of 820,564 carats, or 0·176 carat per load. The pipe has been developed to the 460 ft. level, above which the quantity of ground available for mining is 41,000,000 loads. At this level there is no sign of any contraction of the pipe. The accounts show credits of £2,098,482 on diamond account, and working expenses £749,410. Of the profit, 60% was paid to the Union of South Africa as its share, absorbing £799,400, and £72,205 was paid as taxes. The preference shares received £100,000, being at the rate of 250%, and the deferred shares £440,000, being at the rate of 1,100%.

Champion Reef Gold Mining of India.—This company was formed in 1889 by John Taylor & Sons to acquire property in the Kolar goldfield, Mysore State, South India. From 1894 to 1905 big dividends were paid; afterward, on the ore becoming of lower grade, the rate of dividends was much lower. For the year ended September 30, 1919, no distribution was made. The report for the year ended September 30 last, now issued, shows that, owing chiefly to better conditions ruling for the sale of gold, it has been possible to resume the payment of dividends. During the year, 143,386 tons of ore was treated for a yield of 79,274 oz. of gold. The income from the sale of gold was £376,222, or about £40,000 more than par value. The working profit was £66,575, of which £16,000 was written off for depreciation and £10,000 was placed to reserve. The shareholders received £34,666, or 4d. per 2s. 6d. share, the rate being 13⅓%. The ore reserve at September 30 was estimated at 248,846 tons, a reduction of 44,669 tons as compared with the previous year. Sufficient work has not been done on the new shoot of ore on the 63rd level in Carmichael's Section to warrant a definite estimate of the ore being made. The mine continues to suffer from rock-bursts, which interfere with stoping operations. Recent bursts have caused a drop in the output, and it will be some months before the normal figures are reached once more.

Huelva Copper and Sulphur.—This company was formed in 1903 to work the Monte Romero and other pyrites mines in the south of Spain, previously worked by the Huelva Central Copper Mining Co. Under the management of Henry F. Collins, a smelting plant was erected. The company now produces smelted copper, cement copper, washed pyrites, and complex ore. The report for the year ended June 30 last shows that 66,243 tons of ore was raised, and that 5,862 tons of ore and precipitate was purchased. The output of copper was 1,649 tons, and 3,068 tons of complex ore was sold. The financial result of the year's work was a loss of £5,632. Since the end of the period under review, more favourable contracts have been made for the sale of the copper, complex ore, and washed ore. The company had great difficulty in securing coal and coke, but recently were able to make a contract for supplies with the Penarroya Company. The outlook, therefore, is now more favourable.

Rafinpa (Nigeria) Tin.—This company was formed in 1912 to acquire alluvial tin property 62 miles east of Zaria, Northern Nigeria. This property was not a success, and other properties have been acquired since. An interest has also been secured in stream deposits at Bissoe, Cornwall. The report for the year ended March 31 last shows expenditure of £7,413, of which £1,349 represented interest on loans, as against £2,469 received from the sale of tin concentrate. Since the close of the period covered by the report, the first unit of the treatment plant at Bissoe has been started, but additional plant has been necessary to improve the recovery and to save by-products.

South Bukeru (Nigeria) Tin.—This company was formed in 1910 to acquire alluvial tin property in Nigeria, and other properties have been acquired since. S. R. Bastard is chairman, and C. G. Lush is consulting engineer. The report for the year ended June 30 last shows that the output of tin concentrate was 91½ tons, as compared with 53 tons during the previous year. The sales of concentrate brought an income of £17,356, and the net profit was £95, but if it had not been for a refund of excess profits duty, £2,384, there would have been a considerable adverse balance.

Bullfinch Proprietary.—This company was formed in 1910 to acquire gold-mining property 23 miles north-east of Southern Cross, West Australia. It was reconstructed in 1919. The report for the thirteen months ended September 30 last shows that 70,250 tons of ore was raised and sent to the mill, where 15,560 oz. of gold was extracted. The par value of the gold and silver won was £67,353, to which is added £27,438 for gold premium realized. The working cost at the mine was £77,984, and £6,997 was spent in testing other properties, notably the Victory North, on Hampton Plains. The net profit for the year was £5,806, which was carried forward. A large amount of development work has been done during the period. The reserve is estimated at 50,710 tons, averaging 18s. 8d. per ton at par.

Deebook Dredging.—This company was formed in Victoria in 1913 to acquire alluvial tin properties at the northern end of Bangnon Valley, Renong, Western Siamese States. One dredge commenced work in 1914 and another twelve months later. The property not proving satisfactory, one of the dredges was sold in 1917 to the Ronpibon Extended, and in 1918 negotiations were entered into for the sale of the other dredge to the Taiping Tin Dredging Co. The report for the year ended May 31 last shows that the Ronpibon dredge extracted 282 tons of tin concentrate from 678,000 cu. yd. of ground, and that the Deebook company received £1,125 as dividend on its holding in Ronpibon Extended shares. The company has not been able to acquire any other suitable property, so the directors have decided to distribute the money received from the Taiping company in payment for the dredge as a return of capital. The first instalment of £5,000 has already been paid, and further sums will be distributed as the debt is liquidated.

The Mining Magazine

W. F. WHITE, *Managing Director.* EDWARD WALKER, M.SC., F.G.S., *Editor.*

PUBLISHED on the 15th of each month by THE MINING PUBLICATIONS, LIMITED, AT SALISBURY HOUSE, LONDON WALL, LONDON, E.C.2.

Telephone: *London Wall 8938.* Telegraphic Address: *Oligoclase.* Codes: *McNeill,* both Editions.

BRANCH OFFICES: 420, Market Street, San Francisco. 600, Fisher Bdg., Chicago. 2,222, Equitable Building, New York.

EDITORIAL

THE memorial tablet erected to the memory of members of the Mining and Metallurgical Club who fell in the war was unveiled on March 7, the ceremony being performed by Mr. Walter McDermott, who spoke a few brief but touching words.

THE appointment of Mr. H. C. Hoover as Secretary of Commerce in Mr. Harding's administration is a source of gratification to mining men in all parts of the world. His administrative and financial abilities are appreciated on this side as widely as they are in his own country, and his friends here will unite with those in America in wishing him good luck.

FEW technical societies have enjoyed such rapid and solid success as the Institute of Metals. Though only in its twelfth year, its membership is already 1,350. The Institute already has local sections at Birmingham, Sheffield, and Glasgow, and the latest move has been the formation of a London section. The council also has in view the establishment of local sections at Newcastle-on-Tyne and Swansea.

STUDIES of the behaviour of rocks under great pressure are to be instituted at the University of Wisconsin, which has been able, by means of funds supplied by Mr. W. A. Clark, the copper magnate of Butte and Arizona, to install a hydraulic press capable of exerting a pressure of 200 tons per square inch for prolonged periods of time. The press is fitted with devices for raising the temperature of the material under treatment and for measuring it. It is hoped, with this machine, to investigate many points connected with the metamorphism of rocks.

A branch of the Geological Survey of England and Wales has been established in Whitehaven, with Mr. Bernard Smith as district geologist. The re-mapping of the Cumberland and Furness iron and coal districts is to be undertaken, and investigations are also to be made in connection with lead, zinc, and copper deposits. It is to be hoped that Mr. Bernard Smith will invite the assistance of Mr. J. D. Kendall, whose knowledge of this district is unrivalled. There is one point in relation to these industrial activities of the Geological Survey that requires comment. We refer to the fact that the Survey is now in the control of the Department of Scientific and Industrial Research, a department which does not give the entire results of the researches to the public. In this case we wonder who will get the benefit of such discoveries or recommendations as may be made by Mr. Bernard Smith and his coadjutors.

LAST month reference was made to the alleged injury to marine life caused by the escape of oil-fuel from oil-burning steamers. Many of the statements on this subject are unsupported by direct evidence and are rather vague, so it is desirable to draw attention to definite and reliable pronouncements. For instance, in *Nature* for February 24, Professor Walter E. Collinge, of St. Andrews, writes to the effect that during the past five years numbers of birds which dive beneath the surface of the water in order to obtain their food have been washed up on the Fife coast and elsewhere dead or in a dying condition and covered with a thick coating of oil. In one day he counted more than three hundred kittiwakes, and almost the same number of razorbills and guillemots, and dozens of little auks and puffins.

The Wave-Transmission Rock-Drill.

Last month we published an article by Mr. P. J. Risdon explaining the principle of the wave-transmission rock-drill, and in this issue appears his second article describing the drill and the wave-generator. A general account of the drill was given in our issue of June last, so that there is little left to be said on this occasion. Some of our readers may remember that this drill was tried in South Africa between four and five years ago, and an illustrated note of the trials was made in these pages at the time. War conditions then prevented the continuation of the trials and the making of modifications suggested by the result of these trials. The application of the principle to the synchronizing of aeroplane-engine with hind gunfire took up all the attention of Mr. Constantinesco, the inventor, and Messrs. W. H. Dorman & Co., Ltd., the makers. It is only since the end of the war that attention has once more been given to the drill. In the South African tests one of the weaknesses revealed arose from the use of a spring for effecting the back stroke of the drill. In the improved drill as at present working both the back and the forward motions are obtained by the wave power. A second difficulty in the early days was to find a pipe that

could withstand the high pressures employed. The introduction of the jointed steel piping known as "flexstel" has overcome this drawback. A third problem that caused considerable trouble at first was to find some way of preventing a continuous increase of pressure when the generator was working and the drills were out of use. This source of danger has now been removed by the introduction of the vessels called "capacities" as part of the structure of the generators. Naturally the employment of such high pressures has made it necessary to use considerable thicknesses of metal in the experimental work, for it was obviously desirable to eliminate or reduce risks. Thus the drill as at present made may seem bulky, though it would not appear so by comparison with the heavy drills of a dozen years ago. With experience it will, of course, be possible to reduce the weight eventually. The drill as at present exhibited and in use is applicable for development rather than for stoping, but judging by the success of the firm's rivetters and caulking hammers there is no reason why light stopers and sinkers should not be made. As regards the structure of the drill itself, it will be seen to be extremely simple. There are no valves, and a close fit of the moving parts is not an absolute necessity. The prevention of dust is easily effected, for the water is allowed to pass down the central hole by its own pressure. As regards efficiency, the drill gives blows at a greater rate than the ordinary hammer-drill, and the actual drilling time is proportionately decreased. It is claimed by the makers that the ratio of work done to power put into the drill is much higher than when the compressed air is used. This is quite likely to be so, for only a small proportion of the power of compressed air is utilized in the drill. On the other hand, the power cannot be efficiently conducted along a great length of water pipe, so that it is out of the question to place the generator at the surface and carry the pipes down the shaft. The plan is to bring the power as near the working faces as possible by electric current and to feed anything up to ten drills from each generator. The drill has arrived at a practical stage, and is being put to work at a number of mines and quarries. It has also been shown in full work at the Efficiency Exhibition at Olympia, and it is always to be seen at Messrs. Dorman's works at Stafford.

The Excess Profits Duty.

As briefly recorded last month, the Chancellor of the Exchequer has announced that the Excess Profits Tax is to be abandoned, and for a gloomy enough reason. That is to say, the Government anticipates a severe drop in the receipts from this source owing to the serious depression in trade, and is moreover frightened that the demands for refunds will become overwhelming. The position of the Chancellor is humorously reminiscent of that of the colonel of volunteers of early days, who stentoriously gave the order "Cease firing!" when the corporal told him that the ammunition was exhausted. It is hardly necessary to say much at this juncture as to the expected relief to industry which this withdrawal of the tax will bring, for the depression is so general and the causes for it are so numerous that the removal of one of the causes will have little effect for the time being. It is true that another cause of the dullness, the high cost of living, is showing some signs of abatement. Here and there also wages are being reduced. Both of these movements, however, must go very much farther before the trade position can be appreciably affected, and, finally, the rate of work must be speeded-up enormously.

The Excess Profits Duty is one of those projects which are theoretically ideal but prove in practice to bring evil results in their wake. It was originally introduced for the purpose of equalizing war profits and war expenditure, and as such it was willingly accepted by the nation and by the war contractors. Hardly anybody realized at first that the Act as passed brought every business in the country into its net. Least of all did the mining companies, whose assets automatically deteriorate, imagine that they would be subjected to the same tax as the manufacturing companies and the producers whose assets renew themselves annually. In glancing back through the pages of the MAGAZINE in the latter part of 1915, we renew our recollection of the incredulity and the state of appal which came over the mining profession when this fact was realized. It then became clear that new mining business based on moderate capitalization was virtually doomed. It is true that, subsequently, the terms were made easier by the maximum untaxable return being raised, but this relief was grudgingly given and only to individual companies or groups of companies that brought a petition. It is not too much to say that the present parlous state of metalliferous mining is due to some extent to this penalizing of the beginner. The old mines have continued at work, and are correspondingly nearer to their end, while few new enterprises have been developed. Now that the tax is withdrawn, the effect of the relief will unfortunately be a negligible quantity, for the

prices of metals are so low and the output so difficult to sell that the complete or partial closure of operations is the order of the day and the consideration of new business is out of the question. But this depression cannot last for ever, and when better times arrive the life of the promoter and investor will be sweetened by the knowledge that profits will not be rationed.

Of the many evil results of the tax two have become notoriously conspicuous. One is the flouting of prudent policy by the abstraction on the part of the Government of the profits that should go to reserve funds. The other has been the tendency to dodge the tax by inaugurating extravagant expenditure. Both of these interferences with the strict principles of economics have had very bad influence on business methods. The aberrations from the narrow path have not only been bad for the business man himself, but the infection of his carelessness and extravagance has spread to the worker, and has had the effect of making the worker's present indifference more pronounced. The business man may be able to retrieve the position when the irritating cause is removed, but the worker, not being able to diagnose the symptoms, is not so easy to convert once more to principles of diligence and economy. It is not possible, within the bounds of a short editorial, to weigh all the constituents of the complicated problems of labour, business administration, and taxation bearing on this question of Excess Profits Duty. All that we can say is that the abolition of the tax constitutes an important step toward bringing about cheaper and more profitable operations once more, benefiting capital and labour alike.

The Imperial College's Athletic Ground.

It will be remembered that about a year ago a committee was formed representing the Royal School of Mines, the Royal College of Science, and the City & Guilds College, which are the constituent schools of the Imperial College of Science and Technology, for the purpose of inaugurating a War Memorial. Wisely, the idea of an elaborate structure in stone or bronze was ruled out at the beginning, and it was decided that the records of the men who had fallen in the war should be inscribed on simple tablets to be placed in each of the schools; thus the funds to be subscribed would be available for a more permanently useful memorial, one which would help in the inculcation of an esprit de corps, and at the same time cultivate hardihood, personal daring, and ability to command and obey. South Kensington has for long enough been short in opportunities for athletic exercise, though it is clear that bodily fitness should form part of the equipment of an engineer. The appropriateness of recording war services by doing something to remove this anomaly was therefore obvious, and the committee had no hesitation in embarking on a scheme commensurate with the dignity of the Imperial College. After many inquiries and investigations had been made, a suitable site for the grounds, comprising 23 acres, was discovered between Wembley and Harrow. This district is a well-known habitat for Sports Clubs of all kinds. The Harrow School playing fields are nearby. University College School has it grounds the other side of Wembley. There are numerous first-rate golf clubs within easy reach. Moreover, a number of big business houses have established sports grounds for their employees at various points along the railways that intersect the district. The one drawback is the distance of the ground from the College, but this is a drawback that is unfortunately unavoidable in London. Those who have cars or motor-bikes will not complain of the journeys to and fro, but, it cannot be denied, those who go by train or tram will find the travel tedious. The grounds are most easily accessible from North Wembley station on the Bakerloo line, and the nearest station to the College is across Hyde Park at Paddington. Sudbury Town station on the District Railway is about a mile away from the grounds, and the trains serving this station come from South Kensington by way of Ealing. The grounds can also be reached from Preston Road station on the Metropolitan, and from Sudbury station on the Great Central, though there are very few trains on the latter line. An alternative route is by tram from Edgware Road and Paddington, along the Harrow Road to the Sudbury terminus at the junction of the upper and lower roads to Harrow. Considering London conditions generally, the position of the ground is perhaps not so very inconvenient as it might appear at first sight.

The committee estimated that the total cost would amount to £12,000, the actual price of the freehold of the 23 acres of ground being £7,500. A three months' option was obtained, and a campaign for raising funds was at once commenced. The response was sufficiently encouraging to warrant the committee completing the purchase, by the help of a bank advance on security of a mortgage. It has been possible during the winter to use part of

Map showing position of the Imperial College Athletic Grounds

the ground for football purposes, but funds are required for putting the fields into condition for other sports, and a suitable pavilion is still wanted. In addition it is necessary to pay off the overdraft from the bank. The actual position at the end of 1920 was that £7,000 had been subscribed, while £2,000 had been borrowed. On behalf of the committee we take this opportunity of appealing to all Associates of the Royal School of Mines to send contributions. Those who have not yet responded are asked to give liberally, and those who have already sent something to send a little more. City men who prize technical and administrative ability at the mines and works they control are also encouraged to help in completing the endowment of this necessary phase of engineering education, this branch of education which makes managers and not dreamers.

Deep Shafts.

The paper discussed at the February meeting of the Institution of Mining and Metallurgy put in a concise form the main problems involved in mining at great depths. In this paper Mr. E. H. Clifford gave particulars of the new vertical shaft now being sunk at City Deep for the purpose of attacking ground down to 7,000 ft. In the Mining Digest we reproduce the first part of the paper, dealing with the mechanical details of the shaft, but we have omitted the second part, in which the theory of the ventilation of deep and hot mines is discussed, for the reason that there has been much in the MAGAZINE recently on this branch of the subject. In the first place, Mr. Clifford's account of the ventilation problem at City Deep was given in our issue of September, 1919, and a paper on the problem at St. John del Rey, written by Mr. Eric Davis, was published in the issue of October, 1919. Then the whole subject of ventilation of deep mines was treated by Mr. David Penman in an article in June, 1920. The physiological conditions as induced by heat, cold, moisture, and air currents have been very fully studied by Dr. Leonard Hill, a distinguished London physician, and his writings should be in the hands of all mining engineers interested in ventilation. In particular should be mentioned his reports on the science of ventilation written for the Medical Research Committee and published by the National Health Insurance organization. His modified hygrometer, called the kata-thermometer, has been designed to indicate the cooling effect due to the motion of the air, and thereby to test the physical efficiency of a ventilating current. As regards the general question of cooling by the introduction of dried air, there is one special feature of mining on the Rand that has to be considered; that is to say, if the current is too rapid the natives are likely to be attacked by pneumonia, so there is a very definite limit to

the amount of air-motion allowable. On the other hand, the mines on the Rand are at a great advantage over mines in many other districts. For instance, a large proportion of them are dry, and the incoming air is also dry. Also the rise of temperature with depth is comparatively slow, so that the rock temperature at 7,000 ft. is not likely to be much more than 95°F. The other items deciding the feasibility of deep mining are the amount of pumping necessary, and the ability of the walls to stand the strain due to the weight of the overlying strata. In both cases the conditions at City Deep, and indeed on the Rand generally, are favourable. It is true that in some sections of the Rand the incoming water is large, but these wet mines are mostly in the Far East basin, where mining in depth is not to be considered in the same light as at City Deep, Crown Mines, or other properties in the central Rand.

There are a number of points in Mr. Clifford's description of the new shaft that are of interest. In the first place, he indicates the limit of hoisting from depth in a vertical shaft. A consideration of ruling conditions showed the engineers that 4,500 ft. should be the maximum depth for a single hoist. The only doubt that existed was as to whether the hoisting from 7,000 ft. should not be divided into two equal hoists of 3,500 ft. each, but the point was decided by the fact that the electric winders which were to be installed underground for the lower lift would give out a great amount of heat, and that the ventilation problem would be complicated accordingly. It is often forgotten by engineers that electric motors give out heat proportional to the difference between the total electrical input of the winder and the net work of raising the load. This is an important point in connection with electrical engineering, and mining men and others who have an idea that electrical machinery is entirely self-contained in its influence and action should make note of this circumstance. In many cases, of course, the disadvantage has been overcome by the use of hoists driven by compressed air. At the City Deep new shaft it was found desirable to have the first lift as deep as possible, so that the underground electric winder should be of the minimum size possible. Even then the electrical winders for the lower 2,500 ft. are found to require a ventilating current of 75,000 cu. ft. per minute, or practically one quarter of the total amount of air sent under-ground. The ventilation problem for deep mining is therefore complicated by the necessity for having double lifts.

A second point of interest in the City Deep equipment is that skips are not used, but that double-deck cages are employed, the lower deck accommodating an 8 ton ore car, and both decks being adapted for a hundred men being carried on each trip. Each cage measures 15 ft. 6 in. by 5 ft. 3 in. Instead of there being a divider between the track of the two cages, two so-called dividers are placed one on each side of the shaft, and guide rails are employed instead of guide ropes. It will be seen from the illustrations accompanying the paper that the area of the shaft is put to good advantage. The only other vertical shaft which has been described in our pages is that sunk at the Champion Reef of India, particulars of which were given in the issue of January, 1912. By reference to the drawing then given, it will be seen that there are two cages on one side of the central divider and two skips on the other side, both skips and cages being held in position by guide rails. As regards the discussion as to the advantages of circular shafts as compared with rectangular shafts on the Rand, nothing need be said here, as the question was fully discussed in papers quoted in the MAGAZINE for April and May, 1919. In this discussion it was made manifest that the engineers of the Central Mining group were strongly in favour of the vertical shaft. One of the points in the City Deep design that wants some further explanation is the arrangement of the upper and lower shaft so close together in the vertical line. The idea was no doubt to reduce the lateral movement of the cars at the intermediate station to a minimum, but a number of speakers at the meeting expressed the view that some method more economical in power than the traverser should be employed, and that it would be better to have the shafts farther apart so as to afford leeway in case of any hitch in connection of the machinery of either shaft. For ourselves we do not think that this point is of as great importance as the critics suggested, but Mr. Clifford's reply, giving details on which the decision to adopt this system was based, will be of considerable interest. There is one question which we should like to put to Mr. Clifford: Why does he call Holman sinking drills Leyners? We had an idea that Leyners were made by the Ingersoll-Rand Company. Whether the latter company or Holman Brothers, or either of them, will feel flattered by this mixture of terms we are not prepared to say. In the interests of precision of nomenclature we consider that the word "Leyner" should be a trade mark of the makers of the Leyner drill.

REVIEW OF MINING

Introduction.—The tendency toward lower prices for food and clothing and also toward lower wages is growing more marked. Coal mining and the railways are being released from Government control, and the wages question will be immediately tackled. In spite of the present severe depression in trade, there is a general impression that, as there is an obvious cure, the outlook is not really bad. In metal and mining circles the curtailment of production and the low prices have caused many hardships, but the belief is gaining ground that an approaching lowering of wages and costs and a renewing of demand will restore normal conditions. There is certainly a revival of interest in new mining properties. The political situation with regard to Germany has arrived at another state of crisis, and the severance of negotiations with regard to reparations and the decision of the Allies to occupy certain German towns indicate a stiffening of policy which will be all for the best.

Transvaal.—The triumph of General Smuts at the recent general election has had a steadying effect in business and political circles, and the controllers of the gold mines in particular feel a substantial accession of confidence.

The strike which broke out at Consolidated Langlaagte just before the General Election and spread rapidly among workers at other mines did not last long, for the men's unions were against a general strike and also condemned the precipitate action at Langlaagte. It is settled that the present rate of wages shall continue until the end of the year.

The exploratory work that is being done in the Bantjes property by the Consolidated Main Reef company is giving disappointing results. It will be remembered that this work was done with the object of testing Bantjes ground at a considerably greater depth than the present lowest levels. An exploratory drift in the Consolidated Main Reef ground was carried into the Bantjes, and the intention was to continue it for 3,500 ft. to a point a distance of three levels under the Bantjes incline shaft. About 1,500 ft. has been driven so far, and it is intended to continue for another 500 ft. in hopes of something valuable being found. If the results continue unfavourable, the directors will propose the liquidation of the Bantjes company. During the past month there were rumours that Consolidated Main Reef was intending to absorb Bantjes, but such a scheme would be quite out of the question.

The ore reserves at Modderfontein Deep, as calculated at the end of December last, show a gratifying increase. The figures are 4,100,000 tons averaging 9·4 dwt. over 77 in.; these compare with 3,775,000 tons averaging 9·1 dwt. over the same width at the end of 1919. As recorded last month, the other Far East Rand property of the Union Corporation group, the Geduld, shows a similar improvement.

The Daggafontein mine has had to close down owing to the continued want of success in development and to the exhaustion of working capital. This event was not unexpected by those who had followed development reports, but nevertheless it has given a nasty jar to the mining market. It is only eighteen months since the property was defined, according to the system devised by the Transvaal Government. Reference to a map in our issue of August, 1919, will show that the property consists of 2,059 claims to the east of Springs and south of the Cassel-Clydesdale. One cause of the trouble has been the faulting by dykes, which occurs to a greater extent than is usual in the Far East Rand. As regards finance, the Consolidated Mines Selection Company, on the reorganization in 1916, subscribed £300,000 by the purchase of 300,000 shares at par, and subsequently took £115,874 shares at par. In 1919 the company advanced £250,000 on loan and a further £100,000 was lent last year. The question at the present juncture was whether the loans should be increased, the finances reorganized, or the work suspended until a time arrives when additional funds can be raised under more auspicious conditions. The policy adopted is to let things lie quiet for a while until more geological evidence is obtained in the adjoining Springs workings.

The Consolidated Mines Selection Company has declared its dividend for 1920 at the rate of 1s. 6d. per 10s. share. This compares with 3s. 6d. for 1919 and 3s. for each of the two preceding years. In spite of the fall in the rate, the result can be considered quite good, when the general depression in the Rand market during the past year is considered. In fact in some quarters it was believed that there would be no distribution at all. The company has done notable work in financing Brakpan, Springs, West Springs, and Daggafontein. In all probability it will have to find further funds for the last named.

The liquidators of Village Main Reef have announced a first distribution amounting to

£157,000, being at the rate of 6s. 8d. per share. It is officially estimated that a further 3s. 4d. will be available for distribution.

Two of the old Barnato companies that went into liquidation recently have announced their first distribution of assets. Glencairn is paying 2s. per share and Ginsberg 5s. per share.

One of the depressing elements in the market for South African gold-mining shares has been the uncertainty as to the disposal of enemy shareholdings. The terms of sale offered by the Custodian in South Africa and the Trustee in England were not acceptable to the finance houses, and also they to some extent clashed with each other. These difficulties are now under consideration by the authorities, and as the South African Custodian is in London, conferring with the Trustee and others, some comprehensive and satisfactory scheme for the sale of these shares will no doubt be evolved.

The appeal of Sir J. B. Robinson against the award of the lower court in the Randfontein Estates case has been dismissed, and he will have to pay £460,000. This would be a large sum in ordinary transactions, but the Randfontein Estates is a big finance company, and has lent more than this amount to the Randfontein Central. Nevertheless, the money will be acceptable, seeing that the reorganization of the latter company's mine has cost so much money.

Diamonds.—The depression in the market for the sale of diamonds is becoming more accentuated, and the steps taken by the mines, as reported last month, to prevent over-production are proving by no means sufficient to meet the position. At the Premier mine the work had already been reduced from three to two shifts per day, but news is now to hand that a further curtailment has taken place. Only one shift per day is now being worked. At the De Beers group it has been found necessary to close the Wesselton mine for a time. This closure involves the dismissal of five hundred white employees. The companies, in dismissing the white employees, give them bonuses of £100 each.

The Frank Smith diamond mines are to be closed down, owing as much to the want of success that has attended operations since the re-opening some months ago as to the slackness in the diamond trade. The funds recently subscribed are exhausted, and the present is not the time for raising more capital; otherwise the directors would have tested other parts of the ground. Possibly, when conditions improve, this latter policy will be adopted.

Congo State.—Reference has been made many times in the MAGAZINE to the fact that the river Congo is of little use in navigation owing to shallows and rapids. The Belgian Government recently established an air-way along the river from Kinshasa to Stanleyville for the transport of passengers and goods. One of the difficulties was to provide landing places along the route and to afford relief to aeroplanes that might have to land on account of engine troubles. Many parts of the country are so isolated and the communications so bad that an aeroplane making a forced landing might be irrevocably lost. The plan adopted is to send two or more aeroplanes together, so that if one of them fails the others can notify the fact and bring relief. It is hoped eventually to establish wireless-telephone stations able to communicate with each aeroplane. This service of aeroplanes will eventually be of great service in the prospecting of the Congo State and the regions behind.

Rhodesia.—The output of gold during January was returned at 46,956 oz., and the value at £293,784. As the value per ounce works out at £6. 5s., it is clear that the authorities are not yet able to fix even approximately the premium receivable for each month's production and that the figure for January includes some accumulation of premiums. The other outputs for the month in Southern Rhodesia were: Silver 12,529 oz., copper 240 tons, arsenic 34 tons, tin 3 tons, coal 54,534 tons, chrome ore 5,285 tons, asbestos 2,501 tons, mica 14 tons, diamonds 23 carats.

The labour trouble at the Rhodesian mines has at last been brought to a definite head by the firm attitude of the Mine Owners' Association. For a long time the men's unions have been squeezing the companies one by one, and when each had agreed to new terms the unions commenced another circuit of the mines. On this occasion the trouble started at Shamva, when the men came out on February 19. At the Wankie Collieries trouble arose with regard to the employment of non-union men. Eventually the Mine Owners' Association gave notice of a general policy of lock-out. Already the Lonely Reef has been closed down.

West Africa.—At the meeting of the Taquah Central Mines, the chairman, Mr. T. F. Dalglish, was able to give a much more hopeful account of the labour position in West Africa as affecting the gold-mining industry than he could when presiding at the Taquah and Abosso meetings two months earlier. The Governor of the Gold Coast and the Colonial Office at home have listened to representations, and steps are being taken to meet the gold industry's requirements. Mr. Dalglish's group, in combina-

tion with the Ashanti Goldfields, are devising a scheme, with the consent and assistance of the Government, for recruiting in the northern territories, and a recruiting officer is being appointed who will be fully accredited by the Gold Coast Government. One of the competitors for labour, the cocoa industry, is tending to slacken, and this fact will also benefit the gold mines.

Nigeria.—The collapse of the British West African Trading Company is a matter of regret, not only to the shareholders but to all interested in the prosperity of British trade with Nigeria and the Gold Coast. The company was until a few months ago known as the Tin Areas of Nigeria. Founded on the tin industry, it gradually extended its interests, and there was every prospect of it becoming a sound trading concern. The slump in Nigerian products caused financial difficulties, and an attempt was made to provide further funds by offering debentures in October last. In December a member of a firm of chartered accountants was made receiver and manager, and on February 23 an order was made by the Court for the compulsory winding up of the company. It is believed that not only will the shareholders get nothing but that the debenture holders will not be paid off in full.

Australia.—The position of the Broken Hill mines continues to be serious, owing partly to the low price of metals and partly to the fire at the Port Pirie smelting works. As regards the lead-smelting question, the Sulphide Corporation has undertaken to treat 600 tons of concentrates weekly from the other mines at Broken Hill, making with its own concentrates from the Central mine a treatment of 1,100 tons weekly. In addition the mines will produce 400 tons weekly to be exported for smelting in Europe. It is not believed that any profit will be made by this scheme of operations, and it is only to hold good for two months or so, after which the future policy will have to be decided according to conditions then current. At Port Pirie a temporary roasting plant is to be erected capable of treating 2,000 tons of concentrates weekly, but the cost of roasting will be greater with this plant than at the plant that was destroyed by fire, so it is doubtful to what extent it will be eventually of value in easing the position.

The Broken Hill Proprietary has had trouble at its iron and steel works as well as at Broken Hill. Owing to the shipping strike communication between the smelter and steel works at Newcastle, New South Wales, and the iron ore deposits in South Australia was suspended. The result was that the furnaces went out of blast and subsequently the steel works stopped. Later cables announce that the seamen's strike has been settled, and that the steamers have commenced to run again. Still later cables state that the strike of the men at the company's iron mines has also been settled, so that the position is once more clear.

The Queensland Government is contemplating the building of a railway from Croydon eastward to Georgetown and Forsayth in the Etheridge goldfield, thus connecting the railway starting from the Gulf of Carpentaria with the railways coming westward from Cairns and serving the Chillagoe and the tin districts. The idea is that such a railway would help the Etheridge goldfield, which is now practically deserted. The Einasleigh copper mine, in the Etheridge district, was once well known in London. As regards the building of this new railway, the doubtful question is whether the Government can raise the capital. To put forward such a project at the present time when there has been a hitch in the payment of debenture interest and in the redemption of debentures of the Chillagoe Company does not seem good politics.

New Zealand.—Last month we announced that the Waihi Gold Mining Company was contemplating the return of £250,000 capital in cash and the concurrent reduction of the £1 shares to a denomination of 10s. Notices have now been issued for the holding of the necessary meeting on March 17 for the purpose of obtaining the consent of shareholders prior to the scheme going before the Court for its sanction.

India.—The Mysore Gold Mining Company announces a final dividend for 1920 amounting to 1s. 3d. per 10s. share, together with a bonus of 6d. per share. The total distribution for 1920 is therefore 2s. 6d. per share. In comparing this distribution with those of recent previous years, it has to be remembered that the capital was doubled a year ago, when 610,000 new shares of 10s. were subscribed at par by the shareholders for the purpose of embarking on a comprehensive scheme of development in depth. Thus the 2s. 6d. for 1920, when compared with the 2s. for 1919, represents a correspondingly greater profit. This increase is partly due to various items of cost being covered by the new capital instead of being provided out of revenue; but it is chiefly due to the more favourable terms obtained by the company as regards the disposal of the gold produced.

Malaya.—In January the Federated Malay States Government undertook to buy tin at a

price corresponding to £236 delivered in this country, in order to sustain the local industry. In the middle of February this price was reduced to the equivalent of £204. At the end of February the "peg" was withdrawn altogether, an action which indicates that the Government considers drastic restriction of output the only possible remedy for the present lamentable condition of the tin market.

Cornwall.—The position of the tin-mining industry continues to cause anxiety throughout the county. The men out of work are not able to find other occupations and have to subsist on the doles. The mines owned by public companies have all closed down, and the only question is whether all of them will be able to stand the heavy cost of pumping necessary to keep the workings clear. The Geevor mine is in a particularly unfortunate position owing to shortness of funds. The cause of this arises from the inability of certain shareholders, both individuals and finance companies, to meet the calls due on the new shares issued at the end of 1919. The present position is that the company is £15,000 in debt, and a sum of £5,000 is also required wherewith to continue pumping and to keep the plant in repair. In order to raise these funds, the directors have decided to offer pro rata to shareholders £25,000 8% tax-free debentures redeemable in two years at par. The shareholders who have not been able to pay their calls have agreed to hand over sufficient fully-paid Geevor shares to give a bonus of 25 of these shares to every subscriber of £100 debentures.

The report of East Pool & Agar shows a loss of £19,421, or when depreciation, etc., is allowed, £28,007. This position is entirely due to the fall in the price of tin, arsenic, and wolfram, and the increase in the cost of coal, materials, and labour. The mine has never looked better, and new discoveries of high-grade ore have added substantially to the reserves. The outputs for the year were: tin concentrate 874 tons, wolfram 46 tons, and arsenic 500 tons. As recorded last month, mining was suspended on February 12 until conditions improve.

Canada.—The nickel industry of Canada is suffering owing to the lack of demand for the metal following on the slackening of naval and military construction work. The mines of the British American Nickel Corporation at Sudbury have been shut down. The smelter has also been closed, and the refinery will be closed when the matte in hand has been treated. At the Mond Nickel Company's mines and smelter the men have agreed to a reduction of wages averaging 40 cents per day.

Owing to the low price of silver the Mining Corporation of Canada has closed down its mines at Cobalt. The Kirkland Lake Proprietary reports the discovery of high-grade ore at its Cobalt property, and also promises to issue a report on the Kirkland Lake properties.

Mexico.—The speech of Mr. R. T. Bayliss at the meeting of the Exploration Company contained much that was cheerful with regard to the future of Mexico. He considers that the position in that country has vastly improved during the past year, though there still remains much to be done for improving its economic and industrial stability. He believes that the large public revenue accruing from the export of oil will in itself be sufficient to re-establish the finances on a sound basis, and that this revenue will amply make good the losses due to the fall in the price of silver and the reduced outputs of silver, gold, copper, and lead. As to the fall in silver and the consequent closing of many mines, he sees in this the economic opportunity for bringing wages down once more to a reasonable level. Taking things altogether he considers the outlook hopeful, and feels encouraged to increase the company's interests in Mexican mines whenever reasonable proposals are put before him.

Peru.—Another attempt is to be made to put the San Antonio de Esquilache Mines, Ltd., on its feet again. The present company was formed in 1914 to take over the properties, and under the management of the late Mr. Sydney A. R. Skertchly a large amount of new development was done. The mines are near Puno, and have been producers of silver and lead. The celebrated Caylloma silver mine is in the same district. Mr. Skertchly had not completed his scheme of development before the funds were exhausted, and his death complicated matters. The directors invited the help of Mr. G. R. Bonnard with a view of raising further funds. The present times are not favourable for schemes of this sort, and the proposals put forward by Mr. Bonnard are naturally somewhat onerous, though if all shareholders take their part in the scheme their position will be right enough. The proposal is that £20,000 additional capital shall be raised by the issue of 10% cumulative preference shares, which shall have the right to a cash bonus of £40,000 out of the first profits of the company; alternatively notes might be issued instead of preference shares, carrying the same interest and bonus. This proposal is now being considered by the board and principal shareholders. The latest news from the mine is that a silver-lead orebody has been struck in the long adit.

THE TRANSMISSION OF POWER BY WAVES.

By P. J. RISDON.

(Concluded from the February issue, page 79)

Particulars are given in this article of the new method of transmitting power by wave motion, invented by G. Constantinesco and developed by W. H. Dorman & Co., Ltd. Particular reference is made to the application of the system to the driving of rock-drills.

LAST month I gave an outline of the principle of transmission of power by waves. In the present article I will describe the application of this principle and give details of the construction of the several machines.

THE WAVE GENERATOR.—In a typical 10 h.p. plant (Figs. 6 and 7) the wave generator is mounted upon the same bedplate as the electric motor for driving it. The bedplate is cast in the form of a pair of tanks, one for holding water and the other oil, and may be arranged for bolting to a concrete foundation or for mounting upon two pairs of wheels and axles. If required the plant can be made self-propelling. Upon the bedplate is bolted the generator crank-case, also of cast iron, which accommodates the crankshaft bearings and cross-head guides. The top of the crank-case is provided with an inspection cover which serves as a ventilator and comprises an anti-splash plate. The steel crankshaft runs in phosphor bronze bearings, registered in housings integral with the crank-case. There are two cranks opposed at an angle of 180°. Each crank works a connecting rod, cross-head, and plunger or wave-power ram. On each side of the crank-case is a spherical water chamber known as a "capacity." The outer ends of the plungers, which are fitted with special U-shaped packing rings, enter the "capacities"; the other ends are enlarged and work in the cross-head guides. The plunger has a stroke of 29/32 in., and a diameter of slightly more than $1\frac{9}{16}$ in. The two "capacities" are connected by an overhead pipe, at

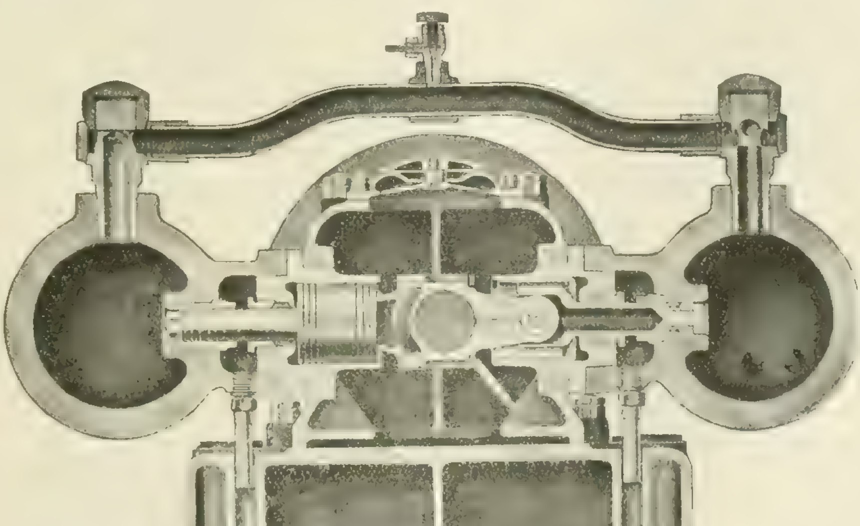

FIG. 6. SECTION OF GENERATOR THROUGH THE "CAPACITIES"

the highest point in which is an air-release needle valve, opened and closed by hand. From each of these "capacities" one or more pipes are led to the machines to be served.

At the forward end of the generator are the oil and water pumps operated by worm gearing. The former provide forced-feed lubrication of all working parts. The water pump is regulated by a pressure-difference valve fitted to one of the "capacities" so as to maintain a constant water supply at a minimum pressure of 100 lb. per sq. in. through the system, even although there may be a leakage or water may be led off to rock-drills. When the minimum pressure in the "capacity" is greater than the pump pressure, the valve is closed, but immediately it falls below that of the pump it opens. This water pump must not be confused with the wave-power plungers or rams, driven by the crankshaft, which set up the wave impulses. A heavy steel flywheel is mounted on the crankshaft between the power unit and the generator.

The generator is so free from vibration that, when at work, a coin can be balanced edgewise upon it. It may be driven by any convenient and efficient means, such as an electric motor or by a steam, oil, or petrol engine. Even belt driving is permissible, but direct-coupled drive without intermediate gearing is preferable when a power-unit capable of the exact requisite speed is available.

It is not necessary to have closer governing than 5% when the transmission line is short, that is, up to about 300 ft., but with longer pipe-lines it is advisable to have the speed of the generator more constant; this, however, automatically adjusts itself within limits. The dimensions and weight of a wave generator compared with those of an air-compressor set, for a given power output, are in the ratio of about 1 to 6 in favour of the wave generator. Two or more generators can be run in parallel, supplying power to the same pipe-line.

Supposing the "capacities" and pipe-lines to be empty, the method of charging is to admit water, which has been properly strained to rid it of loose matter, to the system, by gravity if possible. The generator is started up and the water pump compresses the water to an initial pressure of 100 lb. per sq. in. The air-release valve is then opened to release air from the system, which would otherwise create surges and fluctuating pressures and greatly reduce the efficiency. The air-release valve is then closed again, and thereafter the generator continues to work automatically until further orders. Generators such as that described have been in constant use for experimental and demonstration purposes in Messrs. Dorman's works for several years, during which time it is stated that they have proved the efficiency and economy claimed for them by the makers.

MEANS OF TRANSMISSION. Ten horse-power waves are transmitted through 1 in. piping for a distance of 240 ft. But there is no theoretical limit to the length of transmission. The longer the distance the greater the diameter of pipe necessary, and the practical economic limit is only reached when the initial cost of the pipe-line and the drop in efficiency compare unfavourably with the corresponding items in electrical transmission. But although pipe-lines miles in length are practical propositions, the system accommodates itself to short distance transmission as well, so that a generator and wave motor may form integral portions of a self-contained machine, such as the portable rivetter made on this system.

Although long pipe-lines require to be laid underground or to be otherwise protected against frost in winter time, it is an interesting fact that so long as waves are passing, the water in a pipe-line cannot freeze. Indeed, supposing a main to have frozen up except for a small core of water, waves passed through the system will soon melt the ice. At first it might be supposed that, since ice in the system can be melted and heat is obviously generated, there must be heat losses. But that is not so. Heat generated is absorbed in the act of expansion at the tool end, so that in point of fact after a plant has been at work for an indefinite period, the pipes are quite cold.

From what was said last month, it might not unreasonably be assumed that every wave motor must necessarily be inserted at an exact wave or half-wave length from the generator in order to secure maximum efficiency. Although in ordinary field plants there would be no difficulty about this, in the cases of factories and workshops it would clearly entail inconvenient odd lengths of piping for individual motors in order to bring them to within multiples of half-wave lengths from the generator. This is overcome by a device called a condenser, comprising a small cylinder, of larger diameter than the pipe main, which may be inserted at any point. In this cylinder is a floating piston which is normally maintained in a central position by a spring on either side. From the cylinder a branch is led to a wave motor which it is desired to operate. Struck by the power wave on one side, the piston passes on the impulses to the water on the other side of it. But the cylinder serves as a "capacity,"

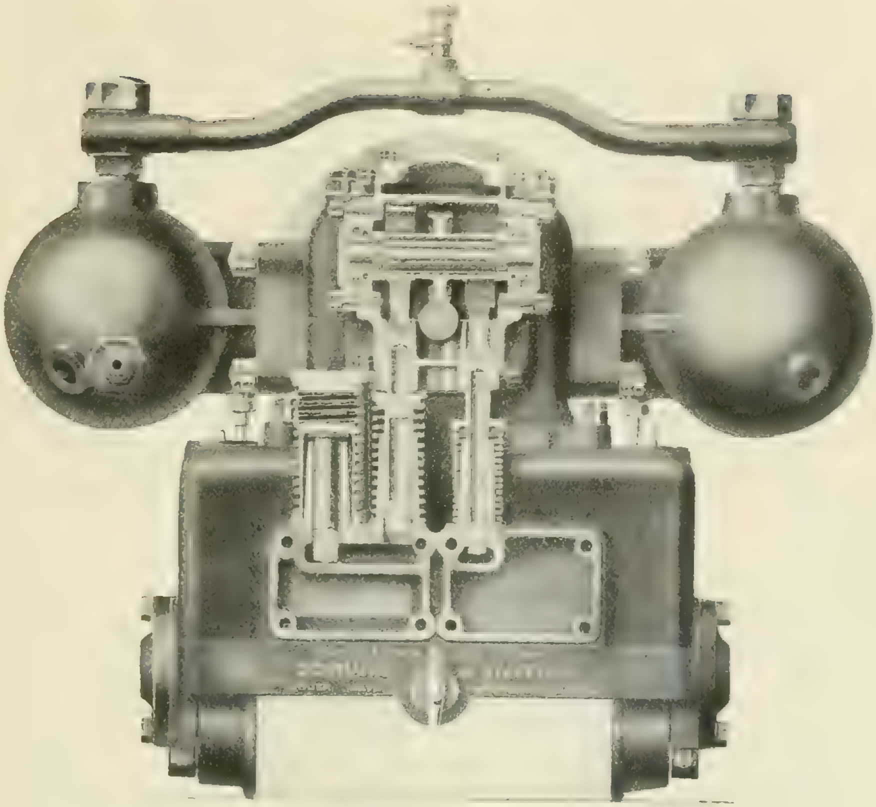

FIG. 7. SECTION OF THE GENERATOR THROUGH THE PUMP GEAR BOX

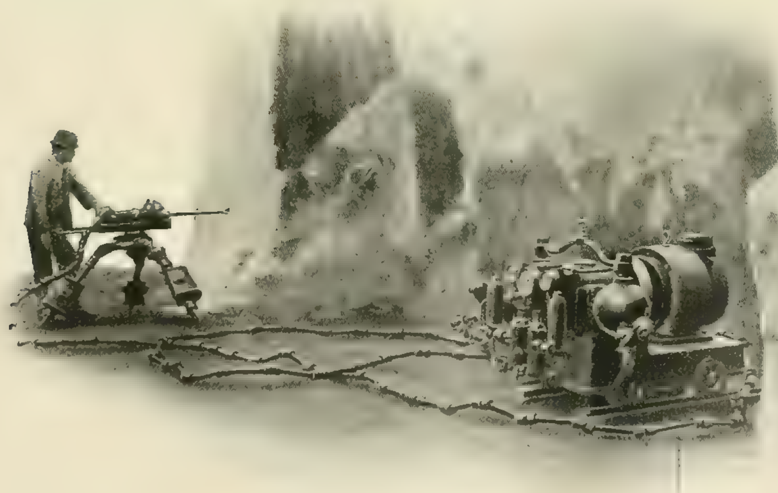

FIG. 8. THE GENERATOR, TRANSMISSION PIPES, AND ROCK-DRILL.

causing a transformation in phase and pressure of the waves. Simple as is the principle involved, each condenser has of course to be carefully proportioned for its particular function.

In motors for percussive tools such as rock-drills the monophase system is obviously the best, as will be explained later. But where it is required to utilize wave power in rotary motors the three-phase system presents distinct advantages, as for example in starting up a motor. This will be instantly appreciated by the electrical engineer, who will also best appreciate the fact that wave-power transmission bears a remarkable resemblance to electrical transmission of power. Indeed so similar are the two systems that there is no expression used in connection with alternating-current appliances which has not its counterpart in wave-power transmission parlance.

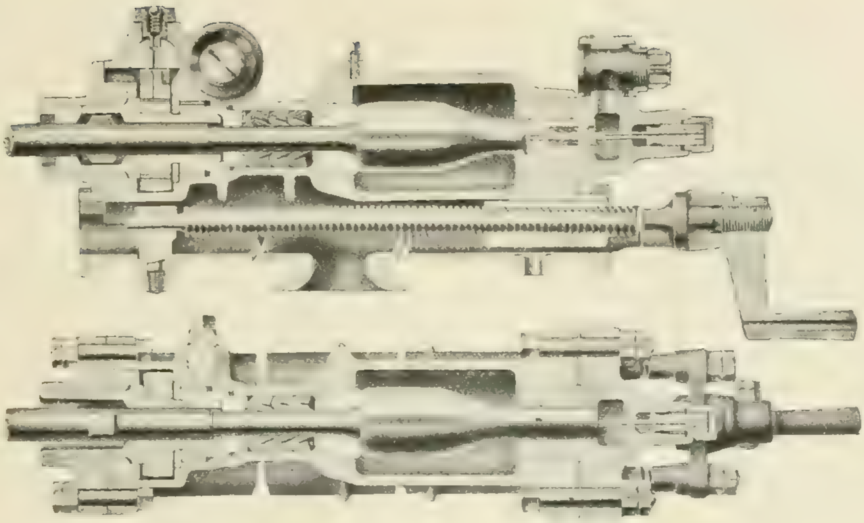
The wave velocity is 4,800 feet per second, the same as the speed of sound in water. This velocity, divided by the number of generator revolutions per second, gives the wave length. Thus with a speed of 2,400 revolutions per minute, $4{,}800 \div (2{,}400 \div 60) = 120$ ft., which is the wave length.

The pipe mains may consist of ordinary hydraulic piping, which, however, has to be rigidly anchored at intervals to minimize vibration. From the mains, "flextel" piping with flexible joints branches to the machines. There is no reason why the pipes should deteriorate in consequence of the waves passing through them, if they are of suitable section and the material is not stressed beyond its elastic limit. Messrs. Dorman have had pipes in constant daily use for the past three years, and state that they have never had a case where a pipe has given out owing to fatigue. All joints are conical and metal to metal, entirely dispensing with all packing materials. The joints can be broken and re-made any number of times without a sign of leakage.

The maximum wave pressure in a typical 10 h.p. installation is 1,500 lb. per sq. in., the mean pressure being 750 lb. In the unlikely event of a burst there is no danger whatever to be apprehended. Higher or lower pressures can be adopted in wave-transmission. The higher the pressure adopted for a given diameter of pipe, the greater is the power that can be transmitted and the higher the efficiency. The conditions for best efficiency in a pipe-line are large diameter of pipes, high pressure, and high frequency; the length of pipe-line must be a multiple of half-wave lengths; the diameter of pipe can be reduced as power is taken off at various points; it is not necessary to provide Y junctions for branch lines, square tees being equally efficient.

WAVE MOTORS.—We have now to consider the conversion of power waves into useful work. As already indicated, the waves could be made to operate a rotary motor by direct impact, but the necessity for self-starting motors renders the direct or monophase system unsuitable for the purpose. Monophase waves are therefore converted into a three-phase system, so that self-starting rotary motors of the three-phase or collector type may be employed. The rotary motors as manufactured by Messrs. Dorman are of simple construction. They may be either synchronous or asynchronous. They are self-starting. The starting torque can be greater than the driving torque. With asynchronous motors it will be equal to or but slightly less than driving torque, but with synchronous motors the starting torque will be low. The power input to the generator is proportional to the work done by the motors, so that if two or three motors in a system are cut out, the power input to the generator is proportionately reduced. If the wave power is not being absorbed by the motor, waves are reflected back to the generator and give up their energy to the generator, thereby reducing the power necessary to drive it. Synchronous motors essentially work at constant speed, and in the case of these machines variable speed of the driven shaft can only be obtained by gearing or slipping devices external to the motor. Asynchronous motors work with a slip, that is, run at a speed slightly less than synchronous speed; loading increases the slip and decreases the efficiency in proportion to the slip. The starting torque with these motors is much larger than with synchronous machines. These motors correspond to the electrical squirrel-cage motors, in which variable speed cannot be obtained without loss of power.

Collector motors are another type which have a maximum torque at starting which will be five times the running torque with machines designed to run at approximately twice the synchronous speed. Variable speed can be obtained most favourably with this type. The single-phase system can be adapted to working rotary motors in several ways: (1) By monophase displacement motor, (2) by ratchet motor, (3) by dividing up the last wave length into three parts and using a three-phase rotary motor. The single-phase system is best for driving resonators, percussive tools, and for long-distance transmission. The three-phase system is best for rotary motors. A static phase converter can be used for converting from



Figs. 9 and 10. Sections through the Rock-Drill.

single-phase to polyphase at any point in the system and is a very simple device.

The best frequency for a particular case is determined largely by the class of work that has to be done. As an example, assume a plant consisting of a single line driving a rock-drill, the most suitable speed is determined by the quality of drill steels in use, and the grade of rock to be drilled. In practice this has been found to be 40 to 50 cycles per second, giving 2,400 to 3,000 blows per minute.

The frequency of the generator is not dependent on the natural speed of the prime mover used, as obviously this can be adjusted by interposing suitable speed reducers or gearing. In practice it is advisable to avoid intermediate gear, so that every effort is made to obtain a prime mover of the desired frequency. The length of pipe plays no part at all in determining the frequency.

Figs. 9 and 10 show a rock-drill in which both the percussive and rotary motions are effected by the same monophase waves, so that absolutely perfect synchronization is ensured although a separate motor is provided for each of the two motions. One end of the hammer works in a bearing and ends in a small chamber filled with water and communicating with the pipe-line. The striking end of the hammer, of smaller diameter, also works in a guide with

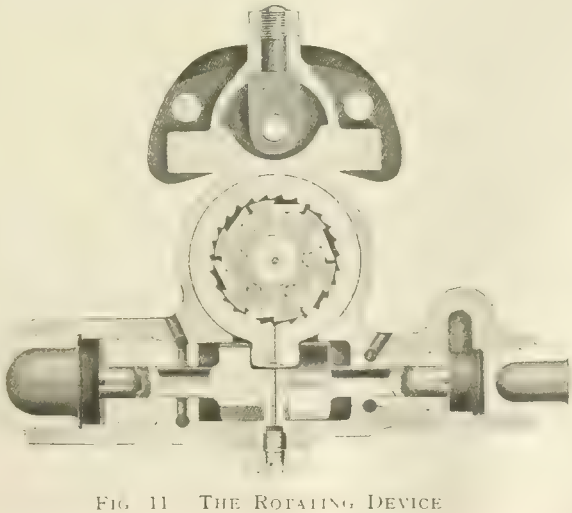


Fig. 11 The Rotating Device

U packings. The body of the hammer is enlarged in diameter and is enclosed in a chamber filled with water. A stop cock, operated by hand from outside, admits power waves, which drive the hammer forward against the end of the drill shank. In thus moving, the striking end of the hammer passes out of the chamber, while the larger end, entering the chamber, compresses the water therein. The result is that the instant the wave impact is ended, the water in the chamber, acting under compression like a spring, drives the hammer back again ready for the next power wave.

At the forward end is a rotating chuck for gripping the end of the drill shank (see Fig. 11). The chuck is fitted with six pawls which engage a circular ratchet, working in a guide, formed by an extension of the main body casting. The ratchet is formed with a lug which is engaged by a slotted plunger, the ends of which work in guides communicating with water chambers. Power waves, admitted at one end, drive the plunger forward, causing a partial turn of the ratchet chuck and drill. Water at the other end of the plunger is compressed and, acting as a spring, drives the plunger back again ready for the next wave. It will be seen that the only springs are the six small pawl springs; otherwise the drill and all its parts are of simple and solid construction, fool-proof and extremely unlikely to get out of order, as there are no finely-fitting parts. A tube passes right through the hammer from a small water chamber at the back end of the machine, and enters the shank of the hollow drill steel about 2½ to 3 in. Through this tube water is forced from the wave power main, the quantity being regulated by a valve.

The perfectly synchronous action of the two wave motors combined with their independent operation is a feature of great importance, as mining engineers will quickly realize.

The complete drill is about the same weight, power for power, as a pneumatic drill. The only lubrication required is an occasional drop of oil on the rotation motor and on the screw-feed. The drill delivers about 2,400 blows per minute. Other types of Dorman rock-drills are worked in a similar manner.

Rivetting hammers are operated by a percussion motor in just the same way as the hammers of rock-drills. In the typical portable rivetting machine we have an example of wave power generated in close proximity to the wave motor without intervening piping. In this instance oil is used instead of water. In the top of the framing is a small dome-shaped chamber into which oil is pumped and maintained at a constant pressure. This chamber communicates through a pressure-difference valve with the generator "capacity" below it, in which the generator plunger or ram impinges on the oil. When the pressure in the "capacity" falls below the normal minimum pressure, the valve automatically opens, and by admitting more oil increases the pressure again, and when the normal pressure is restored the valve closes. The "capacity" communicates with the rivetting hammer beneath it through a hand-operated valve. The hammer is operated in exactly the same manner as the hammer of a rock-drill. The oil pump is located in the upper portion of the frame, which is divided off by a horizontal partition so as to constitute an oil-storage tank. The hammer delivers 2,400 blows per minute. As in all other wave-power appliances, when the rivetter is not in use no power is consumed by the wave generator beyond overcoming friction of working parts, the "capacity" serving to store and give back again all the energy imparted to it. To start the rivetter it is only necessary to pull down the valve handle and admit the wave impulses to the hammer head. The generator may be driven by electric motor, belt, or any other convenient means. The other mechanical features of the portable rivetter need no explanation, beyond mentioning that special provision is made for rapidly adjusting a toothed quadrant so that when the table is raised to the height required it will not rise higher.

EFFICIENCY.—We now come to the all-important question of efficiency. However wonderful an invention may be, its commercial value depends upon how it emerges from the searching test of efficiency which has doomed so many otherwise clever, scientific discoveries. Wave power has been through the test, and has emerged with such success that, if Messrs. W. H. Dorman's statements are even approximately correct (and they are backed by guarantees), the manufacturers of compressed-air plant must be living in anxious times. Probably no one deplores the shortcomings of pneumatic plant and appliances more than the makers themselves. Against a system entailing such wastage, Messrs. Dorman offer wave-power transmission plant with a guaranteed minimum efficiency of 50%, increasing to as much as 85% in many cases.

Messrs. Dorman & Company give practical demonstrations of working plant at their Stafford works, where those interested receive every attention and courtesy. Engineers are recommended to pay a visit to these works to make investigations for themselves.

"FLATS" AND "SOPS" IN FURNESS

By J. D. KENDALL.

The Author discusses the Hematite Deposits known as "Flats" or Bed-like Deposits, and "Sops" or "Pots," with Special Reference to those of Furness.

"FLATS."

In the Memoir of the Geological Survey, Vol. viii., Iron Ores: Hematites of West Cumberland, Lancashire, and the Lake District, we find, in the last paragraph on page 25, the following statement: "A noticeable absence of flats in the limestone of Furness may be due to the superabundance of fissures that lay ready for alteration." Again, on page 41, "In Furness, where flats are usually absent, vertical bores have less chance of success, &c." As there is not a "flat" referred to in that part of the Memoir devoted to Furness—except at Stank, and that reference is from information gleaned from another work—it may, I think, be reasonably inferred that the writer of the Memoir did not know of any. Yet many such deposits have been worked there.

Ore-bodies of this form are usually found as contact-deposits in limestone, on or under beds of sandstone or shale. For example, the flats in the top or first limestone of the Whitehaven district occur either immediately under the Millstone Grit formation, or on the sandstone underlying that limestone. In the first case they have a regular roof of sandstone or shale and an irregular floor of limestone, except where the deposit has the full thickness of the first limestone. There the sole or floor is sandstone. If the ore occurs mainly along the floor of the limestone, the sole will be sandstone and regular, the roof limestone, sometimes very irregular, the ore extending, at places, in "guts" up to the sandstone roof.

When the ore occurs as a flat in the seventh or bottom limestone of the Whitehaven district, it generally has a fairly regular floor of shale and an uneven roof of limestone, but in some places there is a layer of limestone between the ore and the underlying shale, as for example at Ullcoats, Fig. 1, which is wrongly referred to in the Memoir (p. 10) as a fair example of an *irregular* ore-body. On the contrary, it is entirely a flat, notwithstanding the thickening of the ore adjoining the fault. The irregular ore-bodies mainly occurred in the fourth limestone and were quite different in character from the Ullcoats deposit.

The most important flats have been found in one or other of the aforesaid positions, but they occur in all the limestones of the Whitehaven field, and in every case they have either a sandstone or shale roof, or a sandstone or shale floor, the sole or roof in the respective cases being limestone, unless, as was the case at No. 5 pit, Eskett Park, the ore had replaced the full thickness of the limestone and both roof and sole were shale.

The Carboniferous Limestone series of the Whitehaven district being split up into seven distinct beds of limestone, separated by beds of shale or sandstone, there are many horizons on which flats may occur.

The Carboniferous Limestone series in Furness is developed differently from that of the Whitehaven district. In Furness the limestone occurs in practically one solid mass, except near the top, where it is split up by comparatively thin layers of black shale leading up to the base of the Yoredales. It rests on the lower limestone shales, which are underlain by the Basement Conglomerate. It is clear therefore we can expect to find flats only at or near the top or bottom of the limestone, and then only in connection with faults. The most faulted part of the district and the part too that has been by far the most explored, is a belt of the Carboniferous Limestone, less than half-a-mile wide, bordering on the Silurians. I will therefore confine my remaining observations mainly to that area, or rather to part of it, where most work has been done. The limestone there, resting on the Lower Limestone shale, is within easy reach of the surface and numerous flats have been found and worked on the same geological horizon as the flats in the neighbourhood of Egremont and Woodend in the Whitehaven field.

The section in Fig. 2 intersects ten of these flats in the neighbourhood of Lindal Moor, and they are not all by many; but I do not propose to deal with all the flats in the district, merely to give some ground for my complaint as to the conspicuous incompleteness of the Memoir on a matter well known to mining men who have had a general experience of the district. It will be noticed that the flats are all on the downside of the faults, which is very remarkable if the hematite-producing solution came from above. Much the same thing is seen in the flats near Egremont in Cumberland.

None of the faults in the above section is

shown on the map prepared by the Geological Survey, notwithstanding their importance to the explorer. The fact of deposits having been exhausted along certain parts of those faults does not diminish their importance, nor the need for their appearing on a map that is to be of any use to the explorer.

I had occasion some time back, in a review of the Memoir, to point out some of its numerous inaccuracies, but I was reluctant to encroach upon the valuable space of THE MINING MAGAZINE or I could have gone much farther. There is, however, one serious error relating to some of the rocks of Furness, herein referred to, which I ask permission to rectify now. On p. 21 of the Memoir the thickness of the shales and limestones (the Lower Limestone shales), bored through between Dunnerholm and Ireleth, is given as 1,136 ft. The authority for the statement is said to be on pp. 64–67 of the Iron Ores of Great Britain and Ireland. But the thickness there given is 714 ft. 10 in., not 1,136 ft.

"Sops" or "Pots."

On p. 31 of the Memoir we read: "The Furness swallow-holes, after removal of the ore, show a smoothing of the walls that is characteristic of water, and presumably was effected in pre-Triassic times. When a hole ceased to serve as an open conduit, falling material filled the bottom with breccia, including masses of limestone-shales. Disintegrated shale and mud, washed in, formed a rough lining to the whole mass, and in some cases formed a plug at the bottom. Subsequently Triassic sands and clays filled the top of the swallows and covered the limestone-plateau. The mineralizing solution, entering from above, attacked this breccia, which was in a particularly vulnerable condition. As the alteration progressed the new ore packed together and led to the collapse of the roof and the overlying sands in jumbled masses."

Had the Memoir been produced 40 years ago, as it ought to have been, when the writer would have been able to see the deposits before mining operations had obscured their original features, I do not think the above passages would have been written, nor others depending on them. They are very far from explaining the facts to be seen at the time referred to. But if we look at the Park deposit, as represented by Fig. 23 on p. 137 of the Memoir, and reproduced here, in part, by Fig. 3, there is no appearance of the jumble referred to in the Memoir. There are a number of masses of sand and clay, of various sizes, distributed in, and adjoining, the ore-body, but they all occur in positions which could not possibly have been occupied if the supposed overlying sands and clays had collapsed and fallen on to the ore in the manner suggested by the Memoir. Fig. 23 of the Memoir does not show clearly the clay which occurred between the sand and the ore, and between the ore and the surrounding limestone. I therefore give, in Fig. 4, a plan of the Park deposit, at the 50 fathom level, which does show them, as proved by the mining operations prior to 1882.

It is necessary to say here that there was not any material mixing of the different minerals in and adjoining the ore-body. The ore, whether rich or poor, was always ore. There was clay, in places, in the interstices of the fragmentary hematite constituting the mass, which had evidently been washed down from the overlying glacial deposits. There was a large quantity of broken kidney-ore in the deposit and a few small loughs. The sand also was without admixture. So, practically, was the clay, although it had, in places, a few pieces of ore and stone in it. The limestone adjoining the clay was decomposed for about an inch in depth, its hardness decreasing from the unaltered stone toward the clay, against which it was quite friable. The junction of the clay and ore, in every case, was well defined; there was no mixing of the two. Equally distinct was the junction of the clay and sand and that of the sand and ore. At the 60 fathom level the sand was mainly white, but some of it was red. That immediately adjoining the red was mottled. Both red and white were in places quite hard and bedded; the red then looked exactly like St. Bees sandstone. It seemed as if the binding material was being decomposed through exposure. Blocks that were quite hard in the centre became softer outwards and ultimately quite incoherent. Another feature of the deposit which is irreconcilable with the collapses suggested by the Memoir is that many of the blocks of sand and clay are either nearly plumb, or their sides, adjoining the ore, are in parts more or less vertical, as in Fig. 3. If we suppose that the several spaces occupied by sand were originally occupied by limestone which had not been replaced by ore, that subsequently the limestone was dissolved and carried away, leaving cavernous spaces in the ore, into which the red and white sand was afterward deposited, we have a complete explanation of the existence of these sandy masses.

I have seen one or two deposits in another part of the district which consisted of a conglomeration of heterogeneous, non-ferrous, ma-

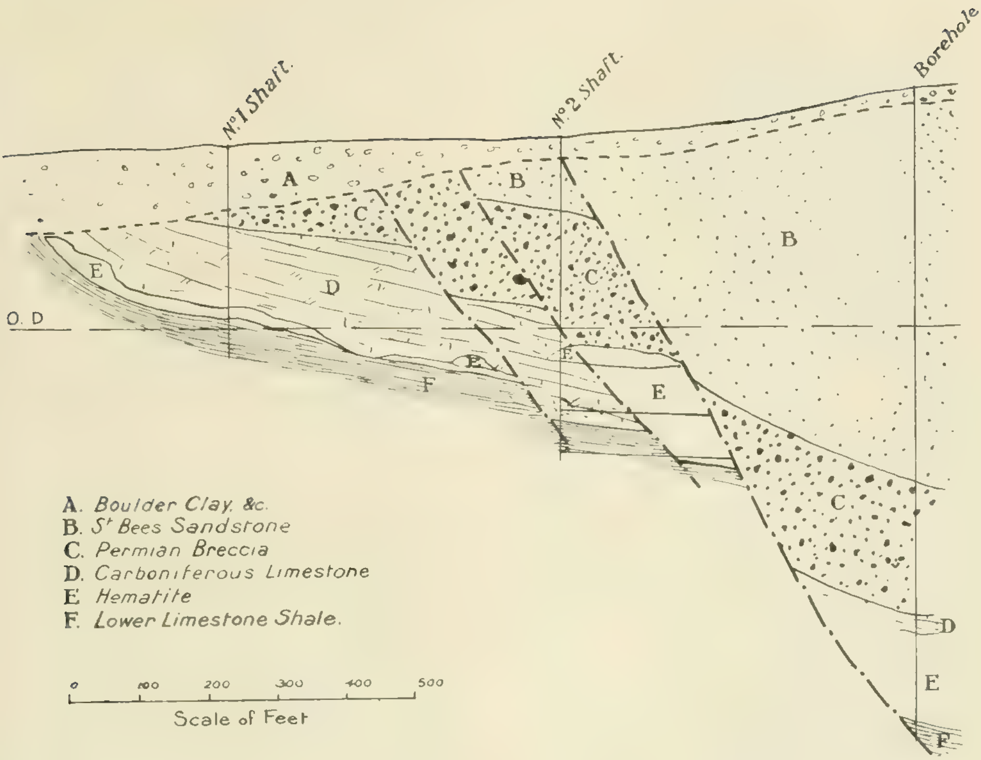

FIG. 1.

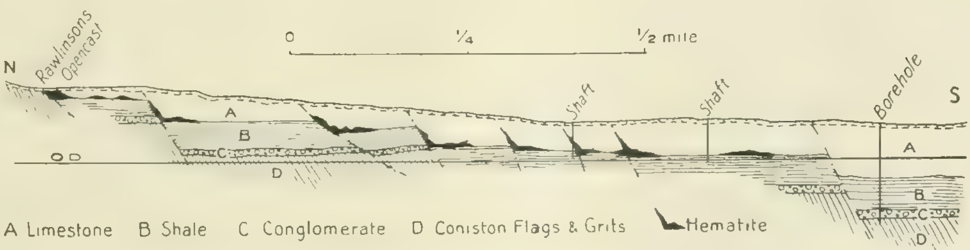

FIG. 2

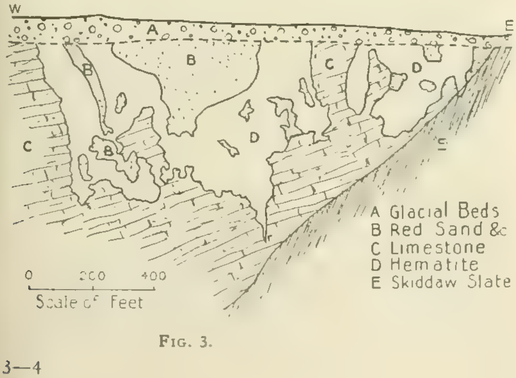

FIG. 3.

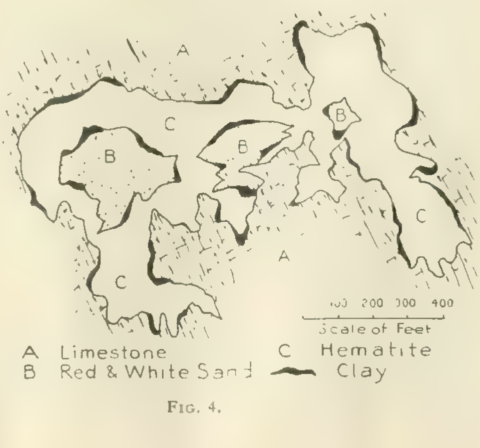

FIG. 4.

terials, through which a considerable quantity of ore was scattered, but they scarcely deserved to be called ore deposits. Yet even they could not be explained in the way suggested by the Memoir. Here is a description of the materials seen in one of them, taken from one of my 1879 notebooks: "The deposit consists mainly of brown and yellow clay, black muck, and angular bunches of what at a distance looks like white sand, but is really partly decomposed limestone. The clay is, in places, laminated, and occurs in layers of different colours, but these are not parallel to any particular plane, dipping and twisting in all directions. Ore—mostly hard pieces—is scattered sparsely through the clay generally, but, in places, it is packed in it in bunches 12 to 14 inches in diameter, the interstices of the pieces, in the bunches, being filled with soft, greasy-looking red ore. The black muck occurs, in patches too, in the brown and yellow clay, and in it there are small pieces of hard, bluish, fibrous ore, 1½ in. diameter, and less. The white sandy-looking material gives to the mass the appearance of a breccia. Each patch of that material is distinctly defined at the edges and they are mostly angular in form" (as in Fig. 5).

In the same notebook there is a description of the ore of a deposit having the ordinary "sop" character. It is as follows: "This deposit consists of closely packed angular fragments of blue ore, up to 3 or 4 inches diameter, and broken laminæ of kidney-ore. In the interstices there is a soft, greasy-looking red ore. In several parts of the deposit I found small loughs—up to 6 inches across—lined with quartz spar. Bunches of clay, 6 to 12 in. across, are met with occasionally in the ore. More rarely, large masses, 10 to 12 yards through them, are come across, which contain small fragments of ore. Clay also occurs interruptedly on the outside of the ore-body, between the ore and the limestone. In places it is only a few inches thick, in others several feet. These clayey masses occur much oftener and more abundantly between the ore and the enclosing limestone—that is, on the outside of the ore—than within it. For a foot or two from the top the ore is much mixed with 'pinnel,' that is, boulder clay by which the deposit was overlain, glaciated stones, in places, lying completely buried in the ore 12 in. or more below the top of it, and numerous pieces of ore occur in and near the base of the pinnel."

There were not any masses of red sand in either of these deposits—which were at Crossgates—as there were at Park and Ronhead. These masses are confined to deposits on the western side of the fault extending southward from Greenscaw. The reason for this will appear later.

All the sops are overlain by boulder clay which, in some cases, is much mixed with the ore, as shown in Fig. 6, a section of Rawlinson's open-cut, near Martin, as I saw it in 1874.

In explanation of the distribution of "sops" the following passage occurs on page 24 of the Memoir: "It may be assumed that in the pre-New Red times the main limestones formed a plateau, extending from the Duddon estuary north of Sandscale to near Lindal (plate III.) and dominated on the south by an escarpment of Yoredale beds. On such plateau swallow-holes and caverns abound, and to this origin the sops of ore which are found from Ronhead to Lindal, and possibly those at Kirksanton, and Water Blean, near Millom, may be ascribed. In New Red times both plateau and escarpment were overspread by New Red deposits, relics of which still survive in several places (pp. 24, 137, 142). In post-Triassic times an uplift ensued, as a result of which the Sandscale-Aldingham fault came into existence. Near Sandscale it coincided with the foot of the Yoredale escarpment, but south of Dalton it broke across it. In Newton and Yarlside mine, farther south, the fault escarpment has the irregular outline of a present-day limestone cliff. The New Red Sandstone is banked up against it."

In the first place let me say that the assumed cliff from Dalton to Lindal does not mark the limit of the sop area. To mention one instance only, as showing the inaccuracy of the assumed line, there was a sop on the boundary of the Highfield House property and that worked by the Dalton Mining Co. which was 1,200 ft. east of the assumed Yoredale cliff.

I cannot find any evidence of this supposed Yoredale escarpment at any of the three points mentioned. Nor can I find any evidence of a fault having the direction of that marked on the map (plate III. of the Memoir) between Sandscale and the railway from Dalton to Furness Abbey. The New Red Sandstone at Yarlside was not banked up against the Yoredales. The two formations were placed side by side by a fault, as shown in Fig. 7. Further, I am satisfied, if such an escarpment, as is assumed by the Memoir, ever existed, it could not have influenced the distribution of any known sops of ore. Fig. 8 is a sketch section of the geological conditions pictured by the above excerpt from the Memoir on a line between Bolton Heads and Park mines, showing a few

FIG. 5.

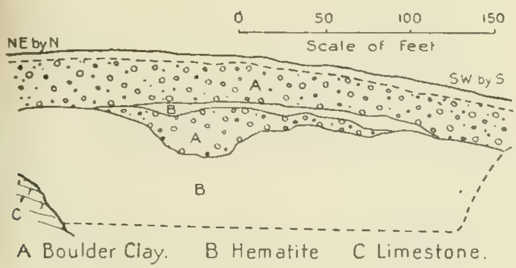

FIG. 6.

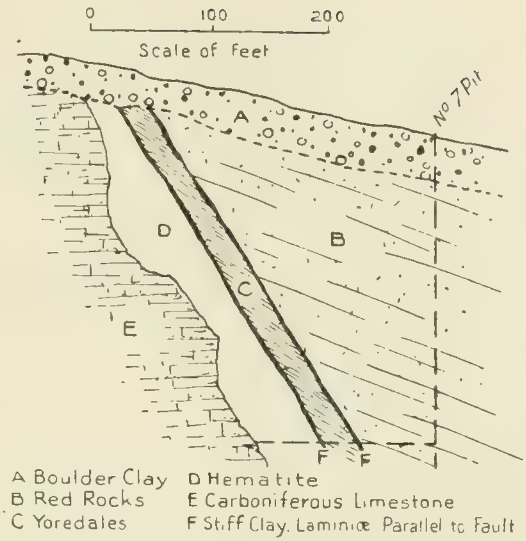

FIG. 7.

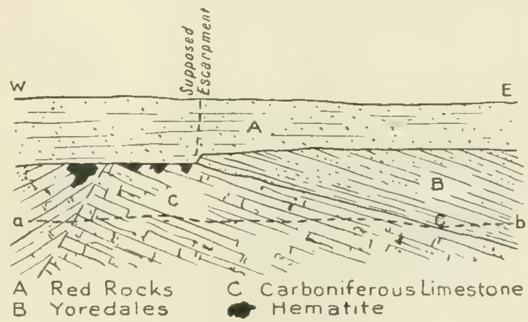

FIG. 8.

sops under the Triassic sandstone. Since the days when those conditions existed, the rocks have been so denuded that the rise edge of the Yoredales is now about a mile and a half east of the supposed escarpment (*c*, Fig. 8) and the surface of the ground is at the level represented by the dotted line *a b*, so that the sops, which were supposed by the Memoir to have been formed immediately below the Red Rocks, were destroyed ages ago, and the postulated escarpment as well.

Let us now see if there is not a simple explanation of the occurrence of the masses of sand and clay associated with the sops that does not require any collapsing caverns, nor the assumption that the ore in the sops was formed otherwise than by the replacement of solid limestone like that in all the other deposits.

In mining the sops, it was not an uncommon thing to break into a cavernous space between the clay or black muck and the limestone. These caverns were sometimes several feet wide and extended up to the boulder clay, as well as horizontally along the deposit. In wet weather great quantities of water came down them into the mine, which were costly and troublesome to deal with. So long as there was a through passage for free circulation there would not be any deposit in such caverns, but if the circulation were impeded there would be a deposit and the cavern would eventually be filled with clay, or clay and black muck, perhaps including a few pieces of ore or stone.

The initiation of these caverns and of all those now filled with clay between the ore and the limestone, or between the ore and sand—whether on the outside of an ore-body or within it—most probably arose as follows: The ore, consisting chiefly of packed fragments, would allow water to circulate through it, and as the outlets would be less than the inlets, the sops would soon be saturated with water, which would extend to the walls in all directions. If that water was acidulated—as it almost certainly would be, being rain water which had passed over decaying vegetable matter—it would attack the limestone walls wherever it reached them, unless they were too silicious, and produce a number of caverns along the outside of the deposits, and, in a similar way, round about the pieces of limestone included in the ore-body. These would afterwards be filled with clay and black muck, the junctions of which with the ore would be quite distinct, as we actually find them.

The clay existing between the ore and the sand must have been deposited before the sand. The limestone which preceded the sand must, therefore, have been removed by dissolution after the clay, adjoining the ore, had been filled into the first-formed caverns, in the same way as the limestone was dissolved out of where the two clay loughs now are in Fig. 1 of "The Distribution of Ore in Depth" (see THE MINING MAGAZINE, May, 1920). It is not necessary that the caverns into which either the clay or sand was deposited should have been of the final size of the clay or sand masses before being filled, as dissolution and formation might be going on at the same time.

I am satisfied the source of the clay was the boulder clay overlying the deposits and the sand came from the large area of Red Sandstone, about half a mile south of the sops, where disintegrated rock occurs abundantly. The top of any of these sops is not more than about 25 ft. above sea level. But the Red Sandstone area to the south of them, from Thwaite Flat to Sinkfall, is from 125 to 225 ft. above that level. To anyone familiar with the swallow-holes of Furness—and the distances to which the water is carried underground by them—the deposition of sand from this source in the sops of Ronhead and Park will appear a very simple process, and one in strict conformity with what we know is going on in the district to-day. There would be an average hydraulic gradient of at least 1 in 30, which is more than sufficient for the purpose, and would allow a good deal of current retardation.

There are not any sand masses in or on the sops occurring in the eastern part of the district, as there ought to have been if the Red Sandstone had been deposited on all the sops alike, as the Memoir supposes. Why is this? The answer is that the ground in the eastern part of the district, where the sops occur, is higher than that in either of the Red Sandstone areas, being from 250 to 375 ft. above sea level, whereas the highest Red Sandstone does not exceed about 225 ft.

Let us now devote a little further consideration to the ore. It is not necessary to look long at any of these sops to be convinced that the ore in them has been subjected to some severe internal strain by which the fragmentary condition now existing was brought about. Incontrovertible evidence of this is furnished by the broken "shells" (concretionary layers) of kidney-ore which form so large a part of most of, if not all, these deposits. In some deposits half of the ore seems to be broken kidney. This form of hematite, as is well known, was formed on the walls of loughs, but there are very few loughs now in the sops, and the broken concretionary layers of the kidney-ore are buried indiscriminately in the fragmentary mass. Another thing to be borne in mind is that the kidney-ore is in places very soft and easily broken or crushed into powder. Here is a note made on the Parkside Co.'s Pennington mine in 1877: "Much of the kidney-ore near the hanging wall is as soft as clay, but has the true kidney structure."

We may now conveniently direct our minds back to the dawn of the Glacial period, when, by the ordinary forces of denudation the upper part of the ore deposits, as originally formed, had been removed, the lower part, or sops, only remaining. The ore in them was then doubtless in the loughy condition of its formation, and the loughs would as certainly be full of water. Soon the intense cold of that period would freeze the water and exert such an irresistible strain on the ore in all directions and from so many centres in each deposit that the ore would be ruptured throughout and the fragmentary condition produced that is so characteristic of the sop-ore to-day.

When the glaciers receded, and acidulated waters began to circulate through the broken ore, the limestone would be attacked and cavities produced in which clay first and afterward sand accumulated. It ignores the work done by the forces of denudation to assume, as the Memoir does, that the red sand was deposited in Triassic times. As shown in Fig. 8, the limestone on which the Red Rocks were laid was hundreds of feet above the Park and Ronhead deposits and disappeared in days that are now far distant even in a geological sense.

The above explanations regarding the sand, clay, and ruptured ore were first put forward in "The Hematite Deposits of Furness" (see Transaction, North of England Institute of Mining and Mechanical Engineers, Vol. xxxi., 1882), but with much less detail than I have thought it necessary to introduce here.

The Ceramic Society, of Stoke-on-Trent, will hold a joint meeting with the French Ceramic Society in May. After the sessions in Paris, there will be excursions to pottery districts in Alsace and Lorraine. Train will be taken to Metz, and afterward Merzig, Mettlach, Sarreguemines, Strasbourg, Soultz-sous-Foret, and Oberbetschdorf will be visited. On the return to Paris a visit to the Sevres porcelain works will probably be arranged.

ON THE ESTIMATION OF PHOSPHORIC ACID BY THE MOLYBDATE METHOD.

By J. E. CLENNELL, B.Sc., Assoc.Inst.M.M.

Difficulties of the Molybdate Method.

The fact that this method has already been the subject of a large amount of experiment is evidence that its execution, as generally carried out, presents considerable difficulties. These difficulties arise from the following causes: (1) the variable composition of the precipitate according to the conditions of precipitation; (2) the solubility of the precipitate in water or in the liquids from which it is deposited; (3) its liability to decomposition on heating; and (4) its hygroscopic nature.

The errors due to these causes may be avoided, or at least minimized, by working under strictly defined conditions, and the writer has recently carried out a number of experiments to determine the correct conditions in the case of such substances as the soluble phosphates of the alkalis and ammonium, and of phosphates like that of aluminium which are insoluble in water, but soluble in dilute acids.

Literature of the Subject.

The chief causes which affect the composition and physical condition of the precipitate are temperature, dilution, acidity, the presence of certain salts such as those of ammonium, and the addition of a larger or smaller excess of the precipitant. Some of these conditions have been fully investigated by other workers, and the following references may be consulted:

Lord and Demorest, "Metallurgical Analysis," 4th ed. (1916), p. 49.

Conditions of Precipitation.

From these writers it may be gathered that the precipitation of phosphoric acid by molybdate solutions proceeds best at a temperature of about 45° C. In cold solutions, the precipitate settles slowly and is difficult to filter, and at a temperature above 60° C. white needles of ammonium tetra-molybdate may be produced. Free HCl or H_2SO_4 must be absent, but a small amount of free HNO_3 is necessary. A large excess of any of these acids causes incomplete precipitation. Ammonium nitrate hastens precipitation, but ammonium chloride and ammonium sulphate retard it. With regard to dilution, Olsen (loc. cit.) states that the phosphate solution should have 100 mgr. P_2O_5 in every 25 cc. Free HNO_3 should be present to the extent of 26 molecules to 1 molecule of P_2O_5. 80 cc. of the standard molybdate (which represents 6 grm. of ammonium molybdate) should be present for every 100 mgr. P_2O_5; this standard solution contains 75 grm. ammonium molybdate and 250 cc. concentrated HNO_3 per litre. Enough ammonium nitrate, 750 grm. per litre, should be added to constitute 15% of the total volume.

Conditions of Settlement and Filtration.

After precipitation, the mixture should be stirred vigorously, say for 5 minutes, and allowed to settle. The time and temperature of settlement are variously given by different writers, but in general not less than one hour is required, and the mixture should be allowed to stand in a warm, but not too hot place, until the supernatant liquid is perfectly clear. It is then filtered. Owing to the solubility of the precipitate in pure water, it must be washed with a liquor containing free HNO_3 and NH_4NO_3. When the volumetric determination by alkali is to be used, a final wash of potassium nitrate is given, to remove all free HNO_3 and ammonium salts.

Final Treatment of the Precipitate.

The final treatment of the precipitate may be varied in many ways, thus:

(1) It may be collected on a weighed filter, washed as directed above, dried, and weighed direct as ammonium phospho-molybdate. This involves all the difficulties due to the solubility, variable composition, instability, and hygroscopic nature of the precipitate.

(2) It may be filtered off, redissolved (say) in ammonia and re-precipitated as magnesium ammonium phosphate, and finally ignited and weighed as magnesium pyro-phosphate. This method avoids the difficulties involved in preparing ammonium phospho-molybdate of constant composition, and the necessity for a weighed filter, but still involves the filtration of the phospho-molybdate and errors due to the solubility of this compound, together with the additional errors involved in the manipulation

of the magnesium compound (solubility of the latter in the mother liquor and impurities retained after ignition to magnesium pyrophosphate).

(3) The ammonium phospho-molybdate precipitate, after filtering and washing, is dissolved in any suitable way and converted into lead molybdate, which is filtered off, ignited, and weighed. This is an indirect gravimetric method in which the amount of P_2O_5 is deduced from the amount of molybdenum used to precipitate it, and involves any error due to variable composition of the original phospho-molybdate precipitate.

(4) Various volumetric methods are in use, in which the P_2O_5 is indirectly determined, either by estimating the amount of alkali which the compound is capable of neutralizing, after it has been washed to remove all free acid, or by estimating the molybdenum content, for example, by permanganate after reduction with zinc and sulphuric acid.

Author's Modification.

I will now give an account of my own experiments. These experiments were made chiefly on methods involving (1) the direct weighing of ammonium phospho-molybdate; (2) the volumetric estimation by consumption of alkali. The preliminary operations are the same in both cases, and the method finally adopted was as follows: A weighed quantity of the salt or a measured quantity of solution is taken, containing about 50 to 75 mgr. of P_2O_5 (the amount should be approximately known by a preliminary test). This is dissolved in water if necessary; if insoluble in water, it may be dissolved in 25 or 50% HNO_3, warming till solution is complete.

Precipitation of Soluble Phosphates.

In the case of a neutral (aqueous) solution, this is then mixed with 60% of its volume of acid ammonium nitrate (3 volumes conc. HNO_3, 2 volumes conc. ammonia, and 7 volumes water). The mixture is heated to 45° C. and mixed with a small excess of 8% ammonium molybdate, previously heated to the same temperature. It is important to avoid a large excess of molybdate. About 33 parts by weight of ammonium molybdate was found to be sufficient for complete precipitation of 1 part of P_2O_5 under the conditions of the test. Olsen's figures imply 60 parts ammonium molybdate for 1 part of P_2O_5, but the present writer finds that any considerable excess beyond that indicated above results in the formation during settlement of a white crystalline deposit containing molybdenum and ammonium, presumably the ammonium tetra-molybdate referred to by Mellor (loc. cit.), even when the temperature is kept strictly within the limits recommended during precipitation and settlement. The mixture is then agitated briskly for 5 minutes and set aside to settle in a moderately warm place for at least 2 hours. It is not desirable to let it stand too long, as in some cases the white deposit referred to gradually forms.

Treatment of Aluminium Phosphate.

In testing aluminium phosphate, 100 mgr. of the finely ground substance, after recent ignition and cooling in a desiccator, is weighed out and warmed with 30 cc. of 50% HNO_3. This generally dissolves it completely in a few minutes. Ammonia, 50% strength, is then added till the mixture is just alkaline, then 30 cc. of the acid ammonium nitrate referred to above, and the mixture boiled. Occasionally a minute residue remains. This is filtered off, dried, ignited, fused with sodium peroxide, extracted with water, and the extract added to the main solution. Experiment showed that this insoluble matter does not, as at first supposed, consist of silica, but is only a part of the aluminium phosphate which, for some cause not ascertained, shows great resistance to the action of the HNO_3. This refractory material usually occurs in acid phosphates, formed by precipitation of aluminium with a large excess of soluble phosphate. When a perfectly clear solution has been obtained, this is heated to 45° C. and mixed with ammonium molybdate at the same temperature. Usually 25 cc. of an 8% solution of ammonium molybdate is a suitable amount, but this must be regulated by the approximately known P_2O_5 content of the substance to be analysed. From this point the procedure is exactly the same as with soluble phosphates.

Gravimetric Determination as Phospho-Molybdate.

For the direct determination as ammonium phospho-molybdate, the clear liquid is decanted through an alundum crucible which has been previously ignited and weighed. Portions of the filtrate are used for transferring the whole of the precipitate to the crucible. The filtration generally proceeds rapidly under slight vacuum, yielding a perfectly clear filtrate, which should not give any further deposit on adding a small quantity of nitric acid or of ammonia, when warmed to 45° C. and allowed to stand. It should also give no yellow precipitate with further addition of ammonium molybdate, but if much of the latter be added, a white precipitate, as stated above, will eventually appear. Three or four washes are now given with dilute acid

ammonium nitrate (5% NH_4NO_3 + 2% HNO_3), filling the crucible up each time and allowing to drain completely before giving the next wash, then 2 or 3 washes of 2% HNO_3 applied in the same way. This is apparently sufficient to extract all soluble impurities and the excess of ammonium salts without redissolving any appreciable amount of the ammonium phosphomolybdate. The crucible is now placed in a drying oven at 110° C. and weighed at intervals till constant weight is obtained. This is the most unsatisfactory part of the whole operation, as prolonged drying is required to eliminate every trace of moisture, and at some point not determined the precipitate begins gradually to decompose at a temperature not exceeding 120°C. The difficulties due to the hygroscopic nature of the precipitate were overcome by weighing the alundum crucible and contents inside a larger vessel with a fairly close-fitting cover (for example, a nickel crucible with lid) to which it is quickly transferred from the desiccator previous to weighing. The weight of precipitate is found by deducting the combined weights of the empty alundum crucible and containing vessel. While accurate results were sometimes obtained by this method, the uncertainty as to the true final weight made the procedure very troublesome. Further tests would be necessary to determine the best conditions for drying the precipitate to constant weight.

Volumetric Method.

After precipitating and settling as above, the clear liquid is decanted through a 9 c.m. paper filter, leaving the precipitate as much as possible in the vessel in which settlement took place. The precipitate is then washed by decantation 5 times with dilute acid ammonium nitrate (5% NH_4NO_3 + 2% HNO_3), then with a 3% potassium nitrate solution, until the washings no longer react with litmus (this requires 5 or 6 washes). All decanted liquor is passed through the filter. The material on the paper is then washed back as far as possible into the vessel containing the bulk of the precipitate by means of a jet of hot water from a wash bottle. N/10 caustic soda is then run slowly from a burette through the paper until every trace of yellow precipitate has dissolved from the latter, collecting in the vessel containing the precipitate. Enough NaOH is added from the burette to dissolve all the precipitate and give a clear solution, distinctly alkaline to phenol-phthalein. The paper in the funnel is then washed 4 or 5 times with small quantities of hot water, which also runs into the containing vessel. The completeness of the washing may be tested by adding a drop of phenol-phthalein to the paper. The mixture is allowed to stand a few minutes, and the excess of alkali is then titrated with N/10 sulphuric acid. The end-point of the titration is not absolutely sharp, perhaps owing to the unavoidable presence of ammonia in the final liquor, but as 1 cc. N/10 alkali represents only 0·307 mgr. P_2O_5, the error from this source is negligible.

Illustrations of above Methods.

(1) By the gravimetric method:

Sodium Phosphate.—A solution was prepared containing 0·5% of the salt, supposed to be $Na_2HPO_4,12H_2O$. Duplicate tests were made on portions of 50 cc. = 250 mgr. of the salt.

BOOK REVIEWS

Geology of Petroleum. By W. H. EMMONS. Cloth, octavo, 625 pages, illustrated. Price 36s. New York and London: McGraw-Hill Book Company.

With the very rapid advancement of oilfield geology, and in view of the enormous amount of geological data accumulated during the course of exploration for petroleum in all parts of the world within the last twenty years, it seems almost incredible that the much-needed textbook on the subject should have been delayed until the present time, more especially when we consider the magnitude of the literature dealing with most of the other important economic aspects of natural science. We do not for one moment suggest that the various technical publications on oil that have appeared in the past have been deficient in quality or wanting in scope, but they have comprised essentially specialized, general, or popular treatises on the subject, and have had their obvious limitations in each case.

To students of petroleum technology, and more particularly to those training as oil geologists, a knowledge of the geologic conditions obtaining in the principal oilfields of the world must be a *sine quâ non* to their technical education; such knowledge in the past must of necessity have been derived from lectures at a training college or from laborious research into the official memoirs of geological survey for oil issued by the several countries concerned, and only those who have applied themselves to such intensive study can appreciate the difficulties and enormous range of the task.

It is not so much a question of the fundamental principles of oil technology, or of the technique of oil and gas production; these branches of the subject are treated exhaustively in many well known publications. But when it becomes a matter of the stratigraphy, structure, mode of occurrence, and economics of a particular oilfield, where is the textbook to which we can refer to save recourse to the more detailed official volumes? The answer to that question is to be found in the publication of the present book, since Dr. Emmons has fortunately decided to deliver his course of Geology of Petroleum lectures (customarily given at the University of Minnesota) to a larger audience, and in offering these lectures in their present form he has filled a gap which both teacher and student will gratefully acknowledge.

The book contains two distinct sections; the first, occupying about one-third of the volume, deals with the first principles of the subject by way of introduction to a broader and more detailed consideration of the world's oilfields, which composes the larger section. On first taking up the volume, we were inclined to glance somewhat cursorily at these first fourteen chapters of introductory matter, because we instinctively expected a repetition of the orthodox story of oil with its origin, causes of migration, accumulation, etc., but certain headings attracted attention, particularly those defining chapters 2, 10, 12, and 14, dealing with surface indications, structural features of oil and gas reservoirs, metamorphism of petroleum by dynamic agencies, and petroliferous provinces respectively. A careful perusal of these led to a closer study of the associated chapters, and any preconceived ideas were soon dispelled by the fresh, convincing manner with which the author handles this introductory subject matter. There is no "laying down the law" in this section, and the elasticity of argument which the author has allowed himself not only gives the reader food for thought, but stimulates interest in the more purely philosophical criteria engendered. In this connection his passing reference to petrographic methods of determination of the composition of reservoir rocks (p. 58) will doubtless set many geologists thinking hard, for though by no means a new idea, such methods, with their far-reaching importance in stratigraphical correlation over small areas, have yet to be more generally applied.

Passing now to the larger division of the work, that dealing with individual oilfield geology, the plan adopted in the description of each region consists of a discussion of the general features, stratigraphy, subterranean structures, mode of occurrence, and economics of oil production, supplemented with more local details of the better known districts within the region under consideration. Maps, horizontal and vertical sections, well records, statistics of production, and explanatory diagrams are lavishly distributed throughout the book, making reference easy and text details simple to understand; in addition, the short bibliography appended to each discussion of a particular region greatly enhances the value of the volume.

It is probably only natural that by far the larger part of this section of the work is devoted to a consideration of the oilfields of the North American continent; possibly in this fact alone are we able to level a slightly adverse criticism of the book, since the proportion of a little over 300 pages to those fields and about 86 to the rest of the world seems at first somewhat incongruous. It must be realized, however, that the amount of technical literature on the North

American oilfields far outweighs that of any other country, and further, the excellence and thoroughness of that literature renders a more universal understanding of the oil conditions of that continent a matter of comparative simplicity. It is therefore not surprising that the descriptions of these fields are fuller and, on the whole, more comprehensive than those of the European, Asiatic, and other fields, a matter which will probably receive adjustment in future editions of the work.

For after all, the educational value of the book is not so much centred about the discussions of American oilfields (notwithstanding their superlative importance in regard to actual oil production) as about the broader geologic principles to be deduced from a study of fields all over the world; it is the author's grasp of this essential which completely justifies the publication of the volume and which proclaims it as unique in the literature of petroleum geology, and we hope that this wider view of the scope of the work will be even more rigidly taken in future editions than in the present case. In this way Dr. Emmons will maintain a live textbook which can never become out of date.

We venture to congratulate both author and publishers on the production of a volume which, for excellence of material and literary merit, deserves a very wide circulation.

H. B. MILNER.

Le Platine et les Gîtes Platinifères de l'Oural et du Monde. By LOUIS DUPARC and MARGUERITE N. TIKONOWITCH. Paper covers, quarto, 542 pages, illustrated, accompanied by an Atlas containing 5 Geological Maps and 8 Plans. Geneva: Société Anonyme des Editions Sonor.

Ever since 1900 Professor Duparc and his scholars have devoted considerable time, intense energy, and genial thought to the study of platinum and platiniferous deposits. The result of their study is contained in the book under review. It is divided into 17 chapters, an introduction, and a list of 123 reference books. All is so extremely thorough and interesting that we do not hesitate to mention the titles of the various chapters.

(1) The Urals from the topographical and geological aspect.

(2) Matrix of platinum, distribution, and general characteristics of the primary platiniferous centres.

(3) Petrography of the primary platiniferous centres; dunite and the peridotites.

(4) Pyroxenites and koswites.

(5) The rocks of the gabbro group.

(6) The vein rocks.

(7) Metamorphic rocks adjacent to the platiniferous eruptive zone.

(8) Distribution of the platinum in the matrix and primary platinum deposits.

(9) Analysis and chemical composition of the platinum compounds.

(10) Secondary deposits and platiniferous alluvials.

(11) Platinum extraction from alluvial deposits.

(12) Description of the dunitic centres in the Urals.

(13) Description of the pyroxenitic centres in the Urals.

(14) The world's platiniferous deposits outside those of the Urals.

(15) Metallurgy of platinum.

(16) Industrial uses of platinum.

(17) Platinum production and general statistics.

Duparc establishes most convincingly that dunite is the pre-eminent matrix of platinum, that pyroxenite may be a matrix of minor importance, and that gabbros for all practical purposes may be considered sterile. The relationship of these rocks is very closely studied, and numerous varieties of transitional character are minutely described. The transitions from one rock into another are closely gone into, and the origin of uralization is explained.

The platiniferous dunite centres, more or less of elliptic shape, are generally within a band of pyroxenite, the latter being surrounded by extensive masses of gabbro. Dunite is held to be a product of magmatic segregation from pyroxenite, the latter being similarly derived from gabbro. Dunite, which consists essentially of olivine and chromite, contains the platinum associated with the latter, but never in sufficient quantity to allow of a remunerative mining of platinum from the rock in situ.

Dunite is a deep-seated rock, and exposed only in consequence of extensive denudation. In the majority of cases, rivers which take their origin in dunite centres, or after passing through these, contain platiniferous gravels; exceptionally pyroxenite centres of definite composition have yielded platinum to river gravels originating in or passing through them. Eleven dunite centres have been located in the Urals, whereas only five pyroxenite ones are known. The crude platinum from different dunite centres is of variable composition and contains from 60·39% to 84·60% of pure Pt, while that derived from pyroxenite centres contains from 78·40% to 88·54% of pure Pt.

One cannot speak too highly of the geologi-

cal and petrographical work contained in the book, and unstinted praise is due to the thorough elaboration of a reliable chemical analysis for crude platinum.

There are also mentioned in the book practical results of applied economic geology, several platinum deposits having been located by the author and his pupils as results of geological field-work. The platiniferous deposits in other parts of the world are summarily described as results of personal inspection by the author or at the hand of trustworthy information.

The criticisms of the book chiefly apply to the purely technical part, where we find measurements given indiscriminately in metric, English, or Russian units. On page 410 the alluvial deposit of the river Bolshaia Sosnowka is given in Russian units, and overleaf (page 412), when describing the river Logwinska of the same river system, metric units are applied. It is also regrettable that platinum contents in the gravels are chiefly given in doli or zolotnik per 100 pood, which do not convey anything to the reader unacquainted with Russian units. At least a conversion table should have been provided. The same remark applies to the plans of machinery where archines, vershoks, metres, and feet are used anyhow. The frequent use of foreign words should be avoided, such as lojok, ouwal, retchniki, peski, and many more, when describing Russian platinum deposits. All such words jar, and moreover cannot be found in a French dictionary. The climax in the use of foreign words is to be found on page 475, where the author says: "The bore-holes carried out by Mr. Orueta on the alluvial deposits of the Rio Verde as well as on other *rios* of the region."

When discussing the methods which have been used for prospecting platiniferous alluvial deposits the author claims that results obtained with the Empire drill are unreliable, and that the drill is quite useless for the prospecting of such deposits. That may be so, yet he describes the drill fully and gives numerous illustrations thereof, and even calls it a diamond-drill in a photo facing page 284.

The only reference of a dry assay for platinum from its matrix is to be found on page 194, where it is mentioned that when platinum is not visible in a rock the latter may be crushed and panned appropriately, or it may be subjected to a lead fusion and the lead button cupelled. This method is, however, far from reliable, and deserves special study and elaboration. The results contained in the tabulated statement of page 195 and referring to platinum contents in dunite are therefore not convincing; further details of the methods employed by the various operators would be generally welcomed.

These criticisms are, however, trifling, and the causes leading thereto can readily be avoided in a revised edition. In all other respects the publication is and will remain a standard text-book on platinum and its deposits. All those interested in that precious metal, be it from the geological, petrographical, or chemical point of view, will welcome this publication of undoubtedly great merit. The geological maps published in connection with the book are models of accuracy and valuable guides for similar investigations. The illustrations generally are clear and good; particular interest attaches to those of famous platinum nuggets which have vanished during the Russian revolution.

A. L. SIMON.

Die Sulfid - Silikatschmelzlösungen, I: Die Sulfidschmelzen und die Sulfidsilikatschmelzen. By J. H. L. VOGT. Vidensk. Selsk. Skrifter, I Mat.-nat. Klasse, 1918, No. 1. 132 pp., with 45 text-figures. Kristiania, 1919.

Die Sulfid-Silikatschmelzlösungen. By J. H. L. VOGT. Norsk. Geol. Tidsskr., vol. iv., 97 pp., with 13 text-figures. Kristiania, 1917.

[This review appeared in the *Geological Magazine* for February, and is reproduced here by permission of the Editor.]

These two publications contain the results of researches undertaken by Professor Vogt during the last few years on the physical chemistry and mineralogy of the sulphides and their relation to silicate melts, with special reference to the slags obtained in the smelting of copper matte. The first-named and larger work forms a third part of Professor Vogt's well-known work "Die Silikatschmelzlösungen"; the second contains a summary of the results set forth in the larger volume, published at an earlier date owing to difficulties encountered on the production of the complete work under war conditions. We are also informed in a preface that another memoir is in preparation dealing specially with the nickeliferous pyrrhotite ore-bodies, which are here only referred to incidentally. The publication of this will be anticipated with much interest by all mining geologists. Professor Vogt also states that he has in hand a nearly completed work on crystallization and magmatic differentiation in the basic intrusive rocks.

The facts here set forth are of the greatest possible interest, both in their technical applications to furnace practice and in their bearing on theoretical petrology and the genesis of the sulphide ores. It is now generally accepted

that silicate melts of whatever composition are completely miscible in all proportions, but with regard to the relations between fused silicates and sulphides the conditions are quite otherwise. Silicate and sulphide melts, as well as silicates and molten metals, possess only very limited mutual solubilities, and in the fused state must form systems of two liquid phases. This proposition is, in fact, self-evident, since it forms the foundation of all smelting processes. Pig iron and slag separate in the blast-furnace, not because the molten iron is heavier than the slag, but because the two liquids are mutually insoluble at the furnace temperature, and the same applies to the separation of sulphide and slag in copper matte-smelting. In both these processes it is obviously desirable to have the cleanest possible separation of metal or sulphide and slag, and it is the investigation of the conditions most favourable to this clean separation that is the chief object of Professor Vogt's researches.

In the first place, it is evidently desirable that the slag should be as liquid as possible, partly in order that it can be drawn off easily and partly to facilitate the sinking of globules of sulphide, which might otherwise remain entangled in a viscous slag. This can be obtained partly by employment of a very high furnace temperature, which is undesirable from the point of view of fuel consumption and running costs. It is found, however, that the viscosity of the slag is very clearly a function of its chemical composition, and especially of its silica percentage. This also has a very important bearing on the solubility of sulphide in slag; this solubility varies inversely as the silica percentage, and directly as the temperature. Very basic slags at a high temperature cause the greatest losses of copper in matte-smelting, and this loss is apparently increased by the presence of much zinc. The practical problem is therefore to find the best working conditions, so that the two opposed factors may compensate each other. The loss of copper inevitable with a liquid basic slag in which the solubility is high has to be balanced against the loss of copper in a viscous acid slag with low solubility, but with a strong tendency to mechanical retention of sulphide. This is a nice example of the application of mineralogy and petrology to problems of the highest practical importance, a point of view which appears to be scarcely appreciated by British petrologists.

Rather more than half of the smaller work here reviewed is devoted to a discussion of the nickeliferous sulphide segregations and their relation to the norites. This is presumably a summary of the forthcoming larger publication before mentioned. It is shown that nickeliferous sulphides have a strong tendency to occur along with rocks rich in rhombic pyroxenes, which are mainly magnesia-iron silicates, rather than with the more calcareous diopside-rocks or normal gabbros. A few sulphide masses of this type are found along with olivine rocks, especially peridotites. The physical chemistry and equilibria of the norite magmas are discussed, and it is shown that many of them approximate closely to eutectic composition (anchi-eutectic rocks). Most of the great pyrrhotite deposits are associated with norites that contain more hypersthene than corresponds to the eutectic limit between labradorite and hypersthene; where felspar is in excess sulphide segregations are much less common. In the cases described it is quite clear that the pyrrhotite crystallized later than the pyroxenes, olivine, and felspars. Incidentally it is of interest that, however quickly cooled, sulphides are always completely crystalline; no such thing as sulphide glass is known to exist. This behaviour is in strong contrast to that of the silicates. Likewise, it appears that owing to the highly mobile nature of fused sulphides, under-cooling does not occur to any appreciable extent, but sulphides crystallize sharply close to their true freezing-point.

All the phenomena attending the occurrence and crystallization of the sulphide segregations and their consanguineous silicate rocks become easily intelligible when it is once fully realized that silicates and sulphides possess very limited mutual solubility, and at the normal temperature of intrusion must of necessity form two liquid phases; this conception greatly helps in the solution of the problem of the genesis of the great nickel deposits of Sudbury and others, a problem which has of late years led to so much discussion by many petrologists, both from its inherent interest and from its great technical importance.

R. H. Rastall.

[Other notices of new books and pamphlets will be found on page 192.]

The Australasian Association for the Advancement of Science was not able to hold its annual meeting at Hobart owing to the shipping strike, and the sittings were held in Melbourne instead. Sir Baldwin Spencer delivered the presidential address, and Sir Edgworth David gave a lecture on "The Romance of Ice." There were special discussions on "The Physical Sciences in Warfare" and "The Constitution of the Atom."

LETTERS TO THE EDITOR

The Greenside Lead Mines.

The Editor

Sir—I shall be glad if you will find space for a reply to your correspondent who contributed to the January issue an article under the heading: North of England Lead and Zinc-Mining in 1920. I think it would only be fair to say in regard to the Greenside Mines that the sole reason the present company do not propose to continue operations after a certain time is because the proposed royalties for the granting of a new lease were too high in the opinion of the directors of the company. It is early yet to say, as your correspondent puts it, that it will permanently close down. Knowing the proposition perhaps a good deal better than your writer, I may say it is not likely to cease as quickly as supposed. The mines have been in operation over a century without a stoppage of any moment, and within the last 60 years have returned to shareholders approximately £400,000, a return equal to 14% on the actual capital. It may not be out of place to say the present company offered to purchase the royalties, but as the price could not be agreed upon, it remained to try and get better terms on a royalty basis, which was not considered favourable at the time. The property is a low-grade proposition, but under a favourable royalty it could carry on even with lead at its present price, and there would be no need to close, as in the case of most mines in this country. The total cost of working for a series of years was under 15s. per ton crude and the mine paid when pig lead was down to £12 per ton. It always carries a large reserve of broken ore underground, which is important to successful mining, and is able to treat 100 tons per day when required to cope with prices.

Too little attention has been paid in the past in this country to working costs above and below ground, and how such can be met in the most efficient way. Lack of development of the ore-bodies and working from hand to mouth, combined with a small output of treatment, lead and zinc-mining in this country is in an unsatisfactory state. It has been a sore point with the average miner that the more he makes on his contract over a certain wage, when the same comes to be re-let the price would in most cases be cut. This has come about by inefficient valuation and not knowing what a worker or workers can do when letting the contract. To my mind no contract should be let on what an individual has done the previous month; the value should be put on the ground to give the worker a living wage from the ground in sight, if he works. I am afraid the managements have done more to kill contract work than the worker himself. Hence the demand for a minimum wage with a go-as-you-please policy. A maximum wage was never too much, but a standard wage irrespective of capacity or intelligence is fatal to all. There are many mines in this country run on modern lines that could show good returns if handled in the right way, and keep capital at home, where it is certainly needed.

As your correspondent was anonymous, I take the liberty of being ditto, and sign myself

Genesis of Cumberland Iron Ores.

The Editor:

Sir—Mr. Kendall, in his letter of January 28, states that I offer no evidence in my letter of December 14 in favour of my conjecture as to the course of geological events in the Lake District. As I said, it is only a conjecture depending on speculative considerations on which we have now and may never have certain knowledge. My conjecture is founded on as little certain knowledge as Mr. Kendall's positive statement that the Carboniferous and later rocks never extended over the Lake District. Perhaps the most that can be said for either view is that it is not impossible.

I am not satisfied with the conclusion Mr. Kendall draws from the facts he states relating to the occurrence of fragments of hematite found in the Permian Breccia near Orebank House, Bigrigg. I do not know if at the time (40 years ago) the possibility of the hematite deposits in the limestone being formed from iron oxide from overlying rocks was in view. Anyone finding fragments of ore in the breccia would naturally conclude they were derived and may not have examined them with special regard to being replacements of limestone fragments. Mr. Kendall states he sliced the fragments 40 years ago for microscopical examination and found no difference between them and pieces taken from the mine, yet some peculiarities in the structure of the fragments from the breccia would, I am advised by geologists, have afforded some evidence as to whether they were derived fragments of hematite or fragments of limestone replaced by iron oxide. The question is too important to be finally decided without the fullest evidence, and I hope Mr. Kendall will pardon me if I say that what was observed so long ago and cannot now be verified does not satisfy me.

It is to be hoped that Mr. Kendall's interpretation is correct as this would open up the probability of hematite being found in the limestone below the Cumberland coalfield in situations where the lines of faulting are known and where deposits might easily be located. My observations in the few cases where the limestone has been proved under and at some distance from the outcrop of the Coal Measures in Cumberland is not in favour of Mr. Kendall's views as to the source of hematite, but this evidence is slight and negative only.

I cannot see any objection to my statement to which Mr. Kendall takes exception that "great light would be thrown upon the genesis and age of hematite deposits by a microscopical examination of the pebbles and fragments found in the Permian Breccia." Perhaps Mr. Kendall thinks that I assume the result would be against his view. One of three results would follow: (a) Found to be derived fragments; (b) found to be replaced fragments of limestone; (c) no evidence either way. As (c) is unlikely, I think I was justified in my statement.

Apart from enclosed fragments of hematite the red staining of the breccia over large areas in the Cleator and Egremont districts is a feature to be noted. This staining appears to be subsequent or secondary. I feel great difficulty in ascribing it to the ascent of iron-bearing solutions or vapours, it is so regular and widespread. It seems more likely to be due to the percolation of water through overlying Trias carrying down iron oxide. The same feature is observed in some parts of the Lancashire coalfield where Carboniferous rocks are stained red for some hundreds of feet in depth where overlain by Trias.

Mr. Kendall seems to think that we might as well suggest a relation between the boulder clay and hematite as between the Trias and hematite, as both formations are found directly overlying deposits of hematite in the limestone. The objections to such a view are: (1) There is not sufficient iron in the boulder clay to account for the masses of hematite in the limestone; (2) boulder clay is not readily permeable to water; (3) in many districts boulder clay is found lying on the limestone with no accompanying deposits of hematite. My contention is that all these conditions are satisfied by the Trias.

In conclusion, my answer to Mr. Kendall's contention that exploration based on a supposed connection between the Trias and hematite in the limestone will result in "a great waste of time and money" has not been met, and I invite him to do so. Even if there is no connection I do not see how the waste comes in.

NEWS LETTERS.

VANCOUVER, B.C.

January 21.

MINERAL PRODUCTION FOR 1920.—In the latter part of January, the Provincial Department of Mines issued the annual preliminary review and estimate of the mineral production of the Province of British Columbia. This report is issued at the commencement of each year for the purpose of placing an approximate estimate before the public, without waiting for the compilation of the actual production, which cannot be completed much before the middle of June. It is understood, therefore, that the figures in the preliminary estimate are subject to revision, but most of them have been found to closely approximate the final figures. The following is the estimate for last year, with the 1919 production, for the sake of comparison:

	1919	1920
Gold, placer..................oz.	14,325	1[illegible],250
Gold, lode....................oz.	152,426	118,176
Silver........................oz.	3,403,119	3,404,926
Copper........................lb.	42,459,339	42,773,660
Lead..........................lb.	29 475,968	21,545,047
Zinc..........................lb.	56,737,651	75,765,268
Coal..................long tons	2,267,541	2,712,228
Coke..................long tons	91,138	68,190

The estimate of the value of the mineral production of last year exceeds the value of the 1919 production by more than two and a quarter million dollars. This increase is due almost entirely to the increased production of coal and zinc. The increase in the production of coal is due very largely to a shortage of fuel-oil during the latter half of the year; a shortage so serious that it necessitated the Imperial Oil Co. closing it refinery, near Vancouver, and the Canadian Pacific Railway converting a number of its oil-burning locomotives into coal-burners. Several coast-going steamships and industrial plants have had to make a similar change. Some idea of how this has increased the demand for coal will be gleaned from the fact that the C.P.R. has had to place an additional order with the Canadian Collieries, Ltd., for 25,000 tons more coal per month. With regard to the zinc figures, it is difficult to see how either those of last year or this year are obtained, unless it is on the assay-value of the ore raised and not on the zinc produced. Whatever the method, it is quite certain that both the 1919 production and the estimate for last year, as given by the Provin-

cial Department of Mines, is fully 45% above the actual production of zinc from British Columbia ores. The Consolidated Mining & Smelting Company produces at least 85% of the zinc made from British Columbia ores, and the company's production was about 26,000,000 lb. in 1919 and 37,000,000 lb. in 1920, as compared with 56,000,000 lb. in 1919, and 76,000,000 lb. given by the local department. There unfortunately is a tendency at times to try to boost output for political reasons, and it looks very much as though that has been the case with the zinc output of the last two years.

As was to be expected, the gold production shows a decrease, the reason for which is quite evident, not only in British Columbia but nearly all over the world. Silver and copper both show an increase in production, but a decrease in value, owing, of course, to market fluctuations. For the same reason the value of the lead production shows an increase, while the production of actual metal shows a decrease. Owing to labour troubles that have tied up the Slocan and Slocan City mines for the greater part of the season, this erstwhile silver district shows a marked falling off in output; fortunately, however, the Dolly Varden and Premier mines, in the north-west section of the Province, have made up the deficit, and the total output is slightly greater than that of the previous year.

Western Canada has not as yet started to try to catch up in building for the four years comparatively idle period during the war, consequently the production of building materials does not show any appreciable increase over that of 1919. Labour prices have been very high, and building materials have been kept at such an exorbitant figure that people have held off reconstruction as long as possible. Just towards the end of the year there was a break in prices of both labour and materials, and considerable activity in building may be looked for during the coming year.

SMELTERS.—The Granby Consolidated Mining, Smelting & Power Company instituted a cut of 75 cents per day in its wage-scale on the first day of the year, and the men agreed to accept it rather than suffer a shut-down, which was the alternative offered to them. Despite the laying-off of some 300 men, Granby is turning out about two and three-quarter million pounds of copper per month: a greater amount than at any time during the past eighteen months. This has been reflected on the shares of the company, which have advanced 10 points above the mini- of 15 reached during November.

The Consolidated Mining & Smelting Company has cut day wages 55 cents per day and those paid by the month $15 per month. The company has an enormous stock of metals on hand, and, as a consequence, has had to notify individual mine-owners that it is no longer able to pay cash for metal contents of ores received, but can give only warehouse receipts. This, it is feared, will mean the closing of a number of the small interior mines, as freight-rates prohibit shipment to smelters in the United States. Probably 85% of the ore treated at Trail comes from the Consolidated Company's own mines, and the output of these is being maintained. During last year some 60,000 tons more ore was treated at Trail than in 1919, and metallurgically, that is with regard to high extraction, it is said to be the best year that the company ever has had. Only a small quantity of copper ore is being treated at Trail, so that Granby may be said to be practically the only copper producer at the present time.

COAL PRICES.—The boards of trade of the big cities have demanded a Government inquiry into the price of coal, the high price of which is checking industry in the Province. In Victoria and Vancouver, according to quality, coal ranges at from $13 to $15 per ton, while in its official estimate the Department of Mines places the price at the pit's mouth at $5. As it is only about an 80-mile haul by water from the Nanaimo mines to Victoria and less to Vancouver, the middlemen appear to be profiteering pretty extensively. No great cut can be made at the pit's mouth, as a majority of the companies have wage-agreements with the men that do no expire until the end of next year.

DOLLY VARDEN.—The Taylor Mining Company has completely closed the Dolly Varden mine for the winter, the directors of the company having decided that, as it is likely that there will be a considerable reduction in the cost of wages next year, it would be cheaper to push development at the same time as production next spring, as it is impossible to ship during the winter months on account of the heavy snows blocking the railways.

VANCOUVER ISLAND COPPER.—The Tidewater Copper Co., which has been developing a property and installing machinery at Sidney Inlet, Vancouver Island, for the past three years, shipped its first consignment of 400 tons of concentrate to the Tacoma smelter last December. Although nothing has been announced, evidently the return from the consignment was found to be insufficient to guarantee the continuance of production with cop-

per at its present price, for the concentrating plant has been closed down, but the development of the mine is being continued.

PREMIER.—The winter shipping at the Premier mine, in the Salmon River district, is progressing favourably, 850 tons of ore, running $400 per ton, already having been shipped, while another 500 tons will be sent to the Tacoma smelter by the next boat. A survey is now being made for an aerial tramway from the mine to tide-water, and when this is completed the Premier will be able to ship throughout the year. The Algunican Development Company will commence to ship ore from the Spider mine early in February. This will make the second shipping mine in the Salmon River district. The ore is a complex one, containing sulphides of zinc, lead, copper, and iron, and is rich in native and ruby silver, some of it running several thousand ounces per ton. About 100 tons of such ore will be shipped during the winter.

IRON ORE.—British engineers have been investigating the iron-ore resources of the Province for the past four months, and it is stated that steps will be taken toward the founding of an iron and steel industry in the neighbourhood of Vancouver during the present season.

TORONTO.

February 10.

PORCUPINE.—The output of gold has been greatly curtailed by reason of the shortage of electric power, which is likely to continue for a few weeks longer until the breaking up of winter brings relief. As soon, however, as power is available a great expansion in the mining industry seems assured, as several properties now closed will be reopened and new companies are preparing to enter the field. At the Dome Mines an important discovery of rich ore has been made at the 1,050 ft. level, where several large ore-bodies have been encountered. Much of the ore will run as high as $20 per ton. The mill is now only working at about one-third capacity. The shareholders of the Davidson Consolidated have decided to sell the property to an English syndicate, which has purchased 1,000,000 shares of the treasury stock at 75c. per share and will buy the stock outstanding in the hands of shareholders at $1·18 per share. Mr. Rowland C. Feilding, consulting engineer, who examined the mine for the British interests, estimates the tonnage of ore disclosed by the work done including probable ore at 350,000 tons averaging $11 per ton recoverable. The mine will be reopened about March 1, and it is intended to erect a 500 ton mill. The annual financial statement of the Porcupine Crown shows profits of $28,788 which, added to the balance carried forward, makes a surplus of $242,532. Milling operations were obliged to be discontinued and development much restricted owing to power shortage. The Premier Paymaster, formerly the Standard, which has been closed for some time after about $100,000 had been expended upon it, is to be reopened, having been financed by Boston capital. The shaft, now down 200 ft., will be sunk to the 500 ft. level. A large ore-body has been developed at the 200 ft. level. The Porcupine Associated Goldfields, Ltd., has been organized, capitalized at $5,000,000, to operate a large group of mining claims in the eastern part of the field. Among the properties included in their holdings are the La Palm and Three Nations, on which a good deal of work has been done, and the Jermy Veteran claim. Altogether the company will control about 720 acres. A large block of the stock is being underwritten by an English syndicate. Negotiations are in progress looking to the amalgamation of the West Dome and the Dome Lake. As the veins of the Dome Lake run into the West Dome it is proposed to work both properties through the Dome Lake shaft. The long-disputed question as to whether the mills of the mining companies were liable to municipal taxation has been finally settled by a decision of the Supreme Court of Ontario, declaring them exempt. As the properties involved in the Porcupine district are valued at about $2,000,000 the matter is of considerable importance to the mining companies.

KIRKLAND LAKE.—The power situation is not so serious here as in the other mining camps, but the supply of electric energy is by no means equal to requirements. The position of the Lake Shore has been greatly improved by development on the 200 ft. and 400 ft. levels, which have been opened up for 2,000 ft. and 1,000 ft. respectively, encountering a large ore-body which is stated to rank with the Porcupine deposits in size and to show higher enrichment. The mill during December treated 1,865 tons of ore for a yield of $34,670. The Wright-Hargreaves mill, with a capacity of 150 tons per day, has been completed and will be put in operation as soon as power can be obtained. The company is expected to be one of the largest producers of the district. The Ontario Kirkland is developing a good shoot of high-grade ore which has been opened up for about 100 ft. on the 450 ft. level. The vein also carries galena, chalcopyrite, and molybdenite. A min-

ing plant is being installed on the Wood-Kirkland and work will shortly be resumed. The vein at a depth of 100 ft. is 4 ft. wide, carrying good commercial ore. At the Hunton-Kirkland rich ore showing visible gold has been encountered in the shaft at a depth of 95 ft. The King-Kirkland has installed a mining plant. A shaft is down 40 ft. on a promising vein. The Kirkland Lake mine during December produced approximately $300,000 in gold. Development is in progress on the 400, 700, and 900 ft. levels. Exploration work is being undertaken on the 400 ft. level to open up the western part of the property where a second ore zone is believed to occur. The capacity of the mining equipment of the Bidgood is being doubled preparatory to the resumption of operations on a large scale. The shaft will be put down from 300 ft. to deeper levels.

COBALT.—With the arrival of spring a general resumption of activity on many of the smaller properties, where operations have been suspended or temporarily curtailed, is anticipated. The lower wage scale which comes into force on the 15th, involving an all-round reduction of 75c. per day, will be an important factor in restoring normal conditions. During December the Nipissing produced silver to the estimated value of $139,882 and cobalt valued at $18,200. The company is in a strong financial position, with cash and bonds in hand to the amount of $3,432,201, and ore and bullion valued at $1,488,802, making a total of $4,921,010. The Kerr Lake has secured an option on the two Hargraves claims adjoining, which will be worked from the Kerr Lake shaft at the 375 ft. and 425 ft. levels. The annual report of the Crown Reserve is a disappointing one, as owing to adverse conditions development had to be discontinued, resulting in a deficit of $72,055. The diamond-drilling campaign, carried on to a depth of 1,500 ft., will be continued to 2,500 ft. An important strike has been made on the first level of the University property of the La Rose, where a vein 2 in. in width carries high-grade ore in addition to milling ore of a good width. At the Bailey a recently discovered vein is being followed up and shows good milling ore over a width of 3 to 4 ft. with some patches of high-grade ore. The Ruby was driven for about 100 ft. on the 110 ft. level, on a vein which has widened to 18 in. and carries native silver, with well-mineralized wall-rock. A new company, the Primo Silver-Cobalt Mining Co., Ltd., has been formed with an authorized capital of $1,000,000 to operate the Barber property, about a mile and a half west of the Montreal River and some ten miles west of the producing area of the camp. The property contains several veins having low silver content and a high percentage of cobalt metal. A mining plant has been purchased.

THE MACKENZIE RIVER OIL FIELD.—The discovery by the Imperial Oil Co. of oil in the Mackenzie River district, close to the Arctic circle, created much excitement and led to the taking up of extensive areas in Western Canada. A rush of prospectors to the north would have taken place but for the action of the Government, which, fearing a repetition of the hardships and disasters attendant upon the gold rush to the Yukon in '98, issued orders that all prospecting parties which were not well provisioned and supplied to encounter the rigours of an Arctic winter should be turned back by the Mounted Police. This has more recently been followed by an Order in Council suspending the negotiations for the disposal of oil lands in the North-West. This is merely a temporary measure to give the Government an opportunity to consider the whole situation in the North-West and adopt a permanent policy in regard to oil development, which it is expected will be made public in a few days. In the meantime the Imperial Oil Co., which had laid out an extensive programme for this season's operations, is holding it in abeyance until the new regulations are promulgated.

MELBOURNE.

January 10.

TASMANIAN OIL-PROMOTIONS.—Owing to exaggerated statements issued by promoters in connection with the so-called oilfields in the Barn Bluff and Pelion areas, Mr. Loftus Hills, Government Geologist, has found it advisable to address a report on the subject to the Secretary of Mines. We quote Mr. Hills in full herewith.

"I would first wish to bring under your notice that statements have been attributed to an officer of the Geological Survey which are not in accordance with the conclusions arrived at and the wording of his report. The article referred to appeared in the *Zeehan and Dundas Herald* of November 30, and was, I believe, copied from the Melbourne *Age* of some days earlier. The article in question contains the following: 'It has been estimated by the Assistant Government Geologist of Tasmania that there are nearly 4,000,000 tons of material very rich in oil and wax.' The only statement published by the Geological Survey in connection with the Barn Bluff coalfield of recent date

is that by Mr. A. McIntosh Reid, in Geological Survey Bulletin No. 30, pages 75-80. Mr. McIntosh Reid does not make the statement that there are nearly 4,000,000 tons of material rich in oil and wax. What Mr. Reid has stated is as follows: 'The quantity of pelionite in the Barn Bluff area has been put at approximately 1,700,000 tons, and that of the second grade cannel is estimated at 2,200,000 tons.' In describing the properties of the pelionite in regard to oil production, the only statement made by Mr. Reid was that the distillation test by Mr. W. F. Ward, Government Analyst, showed that pelionite contained 92 gallons of oil and tar per ton of coal. As the report appearing in the press makes Mr. Reid appear to state that there are nearly 4,000,000 tons of material rich in oil and wax, there is clearly a misrepresentation which is apt to mislead the public.

" I further desire to draw your attention to the fact that a great number of the articles that have appeared in the press within the last few days contain assertions that the material, which they term 'albertite,' occurring in the Barn Bluff field, and the general geological features of the country, are indications of the existence of liquid oil, and it is proposed to raise capital to carry out boring operations. While not desiring in any way to interfere with the investigations of our natural resources, I consider it my duty to draw attention to what are really mistaken ideas in regard to the possibility of the discovery of oil in this area. There is a very great attraction to the general public in the possibility of striking oil, and it would be a most regrettable thing if money were subscribed and wasted on carrying out boring operations in an area where there is no chance of striking liquid oil. The main reason adduced in favour of Barn Bluff area as an oilfield is the so-called discovery of albertite. In the first place, this is not a discovery, as the substance was discovered about thirty years ago. It is described in several publications of the Geological Survey as pelionite, and it is shown in Bulletin No. 13 of the Geological Survey that it is a variety of sapropelic coal. It has since been demonstrated that this substance occurs in practically horizontal beds of Permo-Carboniferous age, and the geological data in connection with this are contained in Bulletin No. 30 of the Geological Survey. All of these sapropelic coals have kerosene-like products, together with more or less tar on being subjected to distillation. The fact that this pelionite, which has been referred to as albertite in the recent press paragraphs, gives oils on distillation is no fresh discovery, and of no special significance. In fact, the kerosene shale of Preolenna and the other sapropelic coals occurring in that district have been demonstrated to yield a similar proportion of crude oil on distillation. The two occurrences are in fact on the same geological horizon, and of the same general geological character. If, therefore, there is to be any attention paid to the possibility of liquid oil, the first investigation should be that of the accessible Preolenna district rather than the very remote Barn Bluff districts. One is tempted to conclude that the very remoteness of the Barn Bluff deposits has lent enchantment to the proposition.

" On the geological evidence in the possession of the Geological Survey, there is no more chance of finding liquid oil in the Barn Bluff-Pelion area than in the Preolenna district. It is further the opinion of the Geological Survey, based on the knowledge of the geological structure, and the geological history of Tasmania acquired during the investigations of the last thirty years, that the conditions essential for the formation and existence of an oil-field do not occur in either of these districts. The reference to pelionite as the mineral albertite is misleading, as albertite occurs in nearly vertical fissures, and is inspissated petroleum, whereas pelionite is a defined coal bed from which the volatile matter has not been distilled. Investigation of the Barn Bluff-Pelion area from the point of view of its potentialities as a coalfield is a justifiable and a very desirable undertaking, but I consider it my duty to point out that money spent in the hope of locating liquid oil will be surely wasted. The persons responsible for the paragraphs recently appearing in the press, and the claims made therein, must produce more evidence pointing to the possibility of finding liquid oil than the reasons put forth up to the present. In the absence of such more definite indications, I am compelled, by a realization of my duty to the general public, to warn them that on the evidence in our possession there is no hope of any discovery of liquid oil in the Barn Bluff-Pelion area."

PROSPECTING FOR COAL IN TASMANIA.—The George Town Coal Prospecting Association has been formed in Launceston to prospect a coal-bearing belt adjacent to the proposed deep-water port at Bell Bay, on the Tamar. A boring machine, supplied by the Government Geologist, Mr. Loftus Hills, and used during the war on the Western front, is being utilized for the purpose of testing the belt. Small seams have been discovered, and

certainly the coal possesses excellent qualities, in fact, equal to anything that has so far been discovered in the State; but the bore alone will reveal whether the seams will develop to such an extent as to warrant the opening up on an extensive scale. Mr. Loftus Hills considers that the coal-bearing nature of the country is well worthy of a thorough test.

NORTH-EAST TASMANIA.—The restricted water supply has caused mining operations throughout the north-eastern district of Tasmania to ease off. The recent slump in the tin market will affect prices very considerably, and the higher prices ruling for all mining requisites, as well as labour, are having a deterrent effect on mining generally. At the Briseis mines sluicing operations have been proceeding at Krushka's Flat main face and also at the Ringarooma high-level drift face, but owing to the shortness of water the latter work has been suspended for the present. Krushka's Flat tin face is looking well. The drainage water is now considerably less, and there is no trouble from that source now, nor will be during the summer months. Preparations for turning the river are in progress, but it will most likely be a year or two before this is accomplished.

PERSONAL.

A. W. ALLEN has been appointed associate editor of the *Mining and Scientific Press*.

D. H. ANGUS has been appointed manager of the Bidgood mine, Kirkland Lake.

J. A. BANCROFT, professor of geology at McGill, is serving for a year as assistant general manager of the Anyox copper mines of the Granby Consolidated Company.

W. J. BARNETT has left for Spain.

H. BERTRAM BATEMAN is back from Arabia.

A. CHASTON CHAPMAN has been appointed president of the Institute of Chemistry.

DR. J. MACKINTOSH BELL has returned to Ontario.

FRANK COGILL has left for West Africa.

C. V. CORLESS is nominated for the presidency of the Canadian Institute of Mining and Metallurgy.

E. H. CUNNINGHAM CRAIG has been making a report on the properties of the Oilfields of Egypt.

G. D. DELPRAT has resigned the general managership of the Broken Hill Proprietary and is succeeded by ESSINGTON LEWIS. Mr. Delprat preserves his connection with the company as consulting engineer.

HENRY S. DRINKER has been made an honorary member of the American Institute of Mining and Metallurgical Engineers. He is one of the original members, and he attended the organization meeting in 1871.

P. ROSS FRAMES is here from South Africa.

CHARLES W. GOODALE is to be presented with the gold medal of the Mining and Metallurgical Society of America.

H. A. GUESS has gone to South America for the Guggenheim interests.

SIR ROBERT HADFIELD has been awarded the John Fritz Medal.

WILLIAM HOSKING is the new president of the Cornish Institute of Engineers.

OWEN LETCHER has been appointed editor of the *South African Mining & Engineering Journal*.

T. H. MOTTRAM has been appointed Chief Inspector of Mines for the United Kingdom.

C. H. MUNRO has returned to the Federated Malay States from America.

C. T. NICOLSON, of the Bucyrus Company, is back from the United States.

R. H. RASTALL, lecturer on economic geology at Cambridge and editor of the *Geological Magazine*, has taken the degree of Doctor of Science in Cambridge University.

J. B. RICHARDSON is back from Bolivia.

J. H. RONALDSON is on his way home from Australia.

EDGAR F. SMITH is the new president of the American Chemical Society. It is worthy of note that he was president of this society twenty-five years ago. He is well known in this country as the author of the book on Electro-Analysis.

D. A. THOMPSON has left for West Africa.

G. H. THURSTON is back from West Africa.

PROFESSOR THOMAS TURNER will deliver the annual May lecture before the Institute of Metals.

T. WEIR is expected from the Bongwelli, Nigeria.

J. S. WETZLAR, the London managing director of the Consolidated Mines Selection Company, has left for South Africa.

W. R. WHITNEY, director of the research laboratory of the General Electric Company, at Schenectady, New York, has been awarded the Perkin Medal.

M. Y. WILLIAMS, of the Canadian Geological Survey, has been appointed professor of paleontology in the University of British Columbia.

J. H. G. WILSON has been appointed manager of the Akim Alluvials, and left England on February 16.

L. B. WOODWORTH has been elected president of the South African Institute of Electrical Engineers.

FERGUS L. ALLAN, manager of the Mexico Mines of El Oro, died in November last.

EWEN CATTANACH, a director of the British Platinum and Gold Corporation, died on February 21.

G. A. PRENTICE died on February 20. He was a notable figure in Stock Exchange circles, particularly in the South African market.

FREDERICK WALKER died on February 18. He was a London solicitor and took part in many successful resuscitations of mining companies that had got into difficulties.

C. F. H. LESLIE, at one time chairman of the Kyshtim Corporation and of the Messina (Transvaal) Development Co., died last month. In early days he was a distinguished cricketer, playing for Oxford and Middlesex, and being a member of one of the English teams visiting Australia.

FREDERICK CLOSE died of tubercular trouble in Switzerland last month. He was a mining engineer of varied experience. He did a great deal for the flotation process in early days. Later he was manager of gold mines in Sumatra. His article in the MAGAZINE a few years ago on the mining developments behind Juneau, Alaska, showed his sagacity of judgment.

G. J. SNELUS died on January 21 at the Jos Hospital, Nigeria, of blackwater fever. Mr. Snelus was serving his first term in Nigeria, whither he proceeded in December, 1919, to take up the assistant managership of the Kaduna Syndicate, Ltd., and Kaduna Prospectors, Ltd., while the manager, J. E. Snelus, his brother, was on leave. He had served in many parts of the world before going to West Africa, and he was particularly well

known on the Continent. From 1895 to 1900 he was in Belgium with the Société John Cockerill, Seraing, Liége, and from there he went to France for two years. He then returned to England, and worked as an inspector of iron and steel. Subsequently he worked in New Caledonia, Spain, Canada, and Cornwall. From 1912 to 1919 he was in Madagascar on gold and graphite prospecting and on land irrigation work. During the war he was British Vice-Consul at Majunga, Madagascar. He was born at Dowlais, Glamorgan, in 1869, and was the eldest son of the late G. J. Snelus, the distinguished steel metallurgist.

TRADE PARAGRAPHS

LOW & BONAR, LTD., of Dundee, send us their chart showing the monthly prices of raw jute and hessian cloth during the past six years.

THE CARBORUNDUM CO., LTD., of Trafford Park, Manchester, send us Catalogue No. 6, dealing with manufactures of carborundum and aloxite, used for grinding and abrasive purposes.

HYATT, LTD., of Thurloe Place, South Kensington, London, S.W.7, send us a new pamphlet describing fully the application of Hyatt Roller Bearings to industrial trucks and trollies.

THE METROPOLITAN-VICKERS ELECTRICAL CO., LTD., of Manchester, send us two pamphlets. One of these, No. 7855/1B, describes buffing motors, and the other, No. 7974/2A, deals with the electrical equipment of cinematograph theatres.

JOHN & EDWIN WRIGHT, LTD., of the Universe Rope Works, Birmingham, are well represented at the British Industries Fair, held at Birmingham. They have a special show of steel ropes used in mine haulage, aerial ropeways, and for oil-well drilling purposes.

GUTHRIDGE, LTD., of Sydney, have recently made further improvements in their "Curvilinear" concentrating table. This table is small but of large capacity. The London agents are James Smith & Partners, Ltd., of 36, Camomile Street, E.C.3, who will supply pamphlets and other information on application.

G. A. HARVEY & CO. (LONDON), LTD., of Suffolk House, Laurence Pountney Hill, London, E.C.4, and Woolwich Road, S.E.7, inform us that their Galvanized Tank List No. 225 is now subject to 60% discount instead of 55% as hitherto; also that their galvanizing rates have been reduced 10%, that is, tariff rates are now being charged without any addition.

THE SULLIVAN MACHINERY COMPANY, of Chicago, and Salisbury House, London, E.C.2, are now giving displays of their cinema show in England. Particulars of this interesting enterprise were published in the MAGAZINE for July, 1920. The pictures give a vivid record of the business of a machine shop where drills and coal-cutters are made, and of the doings of the coal-cutters underground. They might to advantage be shown in coal-mining centres in this country, where they cannot fail to have considerable educative influence, for they show why American coal is mined cheaply.

We have received catalogues from a number of firms making ACETYLENE LAMPS suitable for the purposes of the mining engineer. These names will be of use to many of our readers, so we give them herewith: CARBIC, LTD., 51, Holborn Viaduct, London, E.C.1; THORN & HODDLE ACETYLENE CO., LTD., 151, Victoria Street, Westminster; ALLEN-LIVERSIDGE, LTD., 106, Victoria Street, Westminster; THE PHOS COMPANY, Dalston Lane, London, E.8.; THE WOLF SAFETY LAMP CO., Star Works, Sheffield; and THE PREMIER LAMP & ENGINEERING CO., LTD., Moorfield Works, Wortley, Leeds.

THE HARDINGE COMPANY announces that, owing to expanding business, it has removed its London offices to larger premises at 11, Southampton Row, W.C.1 Satisfactory arrangements have now been made for manufacturing in England on a much greater scale in order to ensure prompt deliveries. The latest design of Hardinge mill embodies important new features, ensuring rapid feed and discharge of large tonnages for both wet and dry grinding. The company has recently issued two new pamphlets, one dealing with the application of the Hardinge mill to the grinding of cement clinker, and the other to the grinding of foundry waste and the reclamation of brass and other metal therefrom.

NOBEL INDUSTRIES, LTD., of 6, Cavendish Square, London, W.1, send us particulars of their exhibit at the British Industries Fair, Birmingham. The details of the exhibit are as follow: Hardware products: metals and metal fittings, Kynoch lanterns and stoves, power presses, thermit welding, metal alloys; ammunition: cartridges by Eley, Kynoch, and Nobel, smokeless powders, components; incandescent mantles: ironclad, shocking machine; bicycles: "all-weather" and "speed" models, 1921 improvements, transfer machine; industrial collodions: "Necol" products, cements, varnishes, lacquers, textile stains. Circulars and other printed matter relating to the foregoing and also to mining and other explosives will be sent on application to the firm's advertising department at 5, Palace Street, London, S.W.1.

METAL MARKETS

COPPER.—The position in copper so far as the fundamental factors are concerned has really not altered during the past few weeks. That is to say, the stocks of the metal still remain more than abundant, while consumption is at a very unsatisfactory rate. An event of some interest recently was the arrangement carried through in the United States between the Copper Export Association and a syndicate headed by the National City and Guaranty companies, whereby some 400,000,000 lb. of copper was financed. Against this bankers were offering 40,000,000 dollars of 8% notes with the copper as collateral. This metal has therefore been set aside as exportable surplus, and a good deal was made of the fact at the time by those interested in getting prices higher. In the long run it has had little effect upon the situation. According to reports to hand from America recently, copper production is being pared down to the lowest limit. The January output figures of several leading mines show that current production is just about 50% of the 1917 rate. This reduction of output must affect the situation in the end. The standard market in London showed some tightness at one time so far as positions maturing up till April were concerned. This was brought about by the covering of bears or possibly of others who had sold short in standard against purchases of refined. These shorts seemed to become somewhat nervous on the report that some American buying had been done here, but after the more pressing demand was satisfied values eased off again. It is understood that with the return of a further section of the miners, the strike at the Rio Tinto mines is now completely over.

Average prices of cash standard copper: February 1921, £71. 0s. 9d.; January 1921, £71. 1s. 4d.; February 1920, £120. 6s. 2d.; January 1920, £118. 4s. 1d.

TIN.—This market continues to fluctuate without any very definite tendency. So far as the consuming industries are concerned, business is very unsatisfactory. The demand from America has been very disappointing, while little can be expected to be done with home

consumers in view of the slack conditions prevailing in the South Wales tinplate industry. A certain amount of inquiry has been seen from the Continent, and a fair amount of business has resulted, mostly apparently in Banka tin. Generally speaking, however, the outlet for the metal among actual users has been small. Meanwhile the standard tin market remains based virtually upon the stocks of Chinese and English tin which are in this country, other brands such as Straits, Banka, Billiton, and Australian metal all commanding premiums. In the middle of the month the Federated Malay States Government reduced the "pegged" price from 115 dollars to 100 dollars per picul. The reduced figure equalled something like £204 for the tin landed here, which therefore was still above the level of the market in this country, and business consequently continued suspended in that quarter. At the end of February the peg was withdrawn altogether, and this had a somewhat depressing effect on the market here. It is understood that the Federated Malay States Government do not intend sacrificing the stocks they have accumulated, but when they will be able to sell them at a profit is hard to say. Batavia has also been reserved, but China has sold from time to time. The net result of these price-pegging policies is that supplies of the metal tend to accumulate, and are apt to become a menace to the market in the future. Meanwhile, in other directions output is being cut down. The Cornish mines, in consequence of the continued fall in the price of tin, wolfram, and arsenic, have suspended operations. What is more important from the market point of view is that cables from Bolivia say that mine-owners there have put into force a sharp cut in production. The January exports were only 1,400 tons (reckoned in fine tin), while those for February, March, and April are only expected to average 700 tons (fine) per month.

Average prices of tin: February 1921, £166. 9s. 1d.; January 1921, £190. 13s. 11d.; February 1920, £395. 16s. 6d.; January 1920, £376. 12s. 8d.

LEAD.—Values of this metal declined materially during the month of February, the price having indeed come to within measurable distance of an ordinary pre-war level. In this respect lead was somewhat of a laggard, the other non-ferrous metals having come already to such prices as usually ruled prior to the war. Probably the value is now below the average cost of production, but with the consumption very unsatisfactory and stocks accumulating the consequent liquidation had the inevitable effect. Business with users, as already indicated, has been very unsatisfactory. At one time the cable-makers took fair quantities, but latterly this tended to ease off, although the decrease may have been partly off-set by an improvement in some other lines. Generally speaking, however, the aggregate consumption is poor. It is understood that production in Spain is being curtailed to some extent by the stoppage of some mines, but it is generally believed that the bigger concerns continue operating, no doubt with the object of keeping their staffs together and preventing unemployment. It is believed that there is a stock of lead in Spain amounting to something like 32,000 tons, though this figure cannot be confirmed. Arrivals continually come in here from that quarter, but it is doubtful if producers are doing more than getting rid of their current production. The production in America last year increased, and business in the consuming industries in that country is apparently very unsatisfactory. Consequently prices there have eased off, the last Trust price quoted being 4·10 cents. It would not, therefore, be surprising to see additional quantities coming forward from that quarter to Europe before long. Meanwhile, owing to the fire at the Port Pirie refinery, Australia is almost out of the picture as a producer. This would be serious were consumption normal, but present supplies are sufficient apparently without shipments from there.

Average prices of lead: February 1921, £21; January 1921, £23. 12s. 6d.; February 1920, £50. 12s. 9d.; January 1920, £47. 7s. 1d.

SPELTER.—This market has been showing a moderately steady tendency recently, the fluctuations being really only of a minor character. The general situation shows little material alteration. Business with consumers still remains very unsatisfactory, and, although at times there are signs of inquiry waking up a little bit, this is seldom sustained. Some demand, however, has been seen from the East and metal has been sold for shipment from here to Japan. America has not continued her buying policy here, owing no doubt to the improvement in the rate of dollar exchange, coupled with the easing of the price in America having

made such business unprofitable. Germany sells here from time to time, and in view of the amount of metal that has been sold here by that country the market may be said to have held up very well considering the fact that consumers are taking so little. There still seems to be a good deal of metal to come forward from Germany, and it remains to be seen whether the market here can absorb this without prices suffering. Belgium does not offer very much, and is considerably reducing production. It is expected that by March the production will only amount to about 4,000 tons, or half the December output. Were trade anything like normal the existing supplies of spelter would no doubt get quickly used up, as there is certainly no superabundance for normal times, but with industry everywhere as stagnant as it has been, there is more than enough for present requirements.

Average prices of spelter: February 1921, £25. 5s. 5d.; January 1921, £25. 15s. 7d.; February 1920, £62. 3s. 6d.; January 1920, £59. 10s. 4d.

ZINC DUST.—There is little fresh to report regarding this market, which continues very quiet. High-grade Australian stands at about £70 to £80 per ton, with American at £65, and English at £75. Continental material can be had at lower figures.

ANTIMONY.—English regulus continues at £37 to £40 for ordinary brands, and at £38. 5s. to £42 for special brands. Foreign regulus has been quiet. Down to £23 c.i.f. has been done for shipment from the East.

ARSENIC.—Business continues very idle, and the current quotation for Cornish white is nominal at £50 per ton delivered.

BISMUTH.—The price has had a sharp drop to 7s. 6d. per lb. Business is quiet.

CADMIUM.—The current price is about 6s. 3d. per lb.

ALUMINIUM.—The price has been reduced to £150 per ton for home and export.

NICKEL.—The price has been reduced to £200 per ton for home and export.

COBALT METAL.—The price has been reduced to 20s. per lb

COBALT OXIDE.—Black oxide stands at 16s. and grey at 17s. 6d. per lb.

PLATINUM AND PALLADIUM.—These metals can be had at around £17 per oz., although more is asked for small quantities or in manufactured form.

QUICKSILVER.—The market has continued quiet, but in the absence of selling pressure values have been steady at about £12. 10s. to £12. 15s. per bottle.

SELENIUM.—The price stands at 10s. 6d. to 13s. per lb.

TELLURIUM.—The quotation continues at 90s. to 95s. per lb.

SULPHATE OF COPPER.—Business is quiet, and prices are easier at about £34 to £36 per ton.

MANGANESE ORE.—Values are lower at about 1s. 9d. to 1s. 10d. per unit c.i.f. U.K. for Indian grades.

TUNGSTEN ORES.—The current quotation for wolfram is about 14s. per unit c.i.f.

MOLYBDENITE.—85% stands at 57s. 6d. to 65s. per unit c.i.f. U.K.

CHROME ORES.—48% is quoted at about £5 c.i.f. U.K.

SILVER.—On February 1, the price of spot standard bars was 34½d. per oz., values improving to 37⅞d. on the 3rd. Subsequently 31⅜d. was touched, the price at the end of the month being 33d.

GRAPHITE.—Soft velvety flake 85 to 90% is quoted at £60 to £80 per ton. Madagascar 80 to 90% is quoted at £20 to £25 per ton.

IRON AND STEEL.—The past month has again been far from satisfactory to the British iron and steel trades. Pig iron makers have found their product almost unsaleable owing to the hesitation on the part of buyers to place orders here owing to slack trade and the lower prices quoted by the Continent. Prices have in consequence been reduced, No. 3 Cleveland G.M.B. standing at £7. 10s. for the home trade and £7. 15s. for export. Makers are being forced to curtail their output, and already sixteen Cleveland blast-furnaces have been blown out. In the finished branches of the trade many works are closed, or partly closed, owing to the lack of orders, and trade is gradually being brought to a standstill. Drastic reductions in prices have made their appearance, being desperate efforts to keep plants going, but orders are few and far between. The competition from the Continent is exceedingly keen, not only with this country, but there is also much scrambling among the Continental producers themselves to secure any business that is going, with the result that prices are ruthlessly cut.

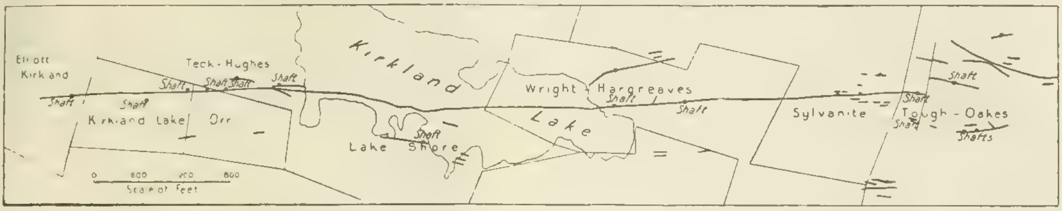
THE MINING DIGEST

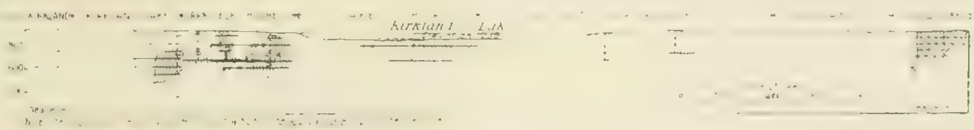
A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also notices of new books and pamphlets, lists of patents on mining and metallurgical subjects, and abstracts of the yearly reports of mining companies.

THE KIRKLAND LAKE GOLD MINING DISTRICT.



PLAN SHOWING PRINCIPAL WORKINGS AND LODES AT KIRKLAND LAKE.

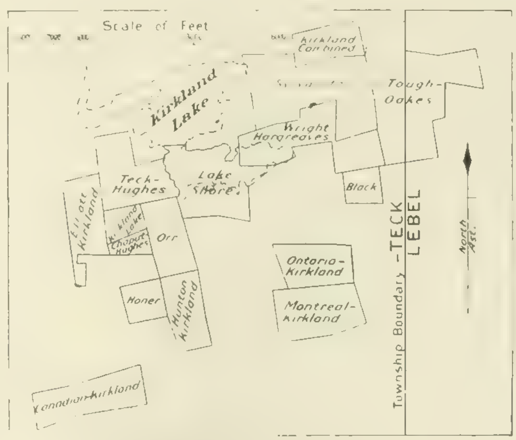


SECTION OF PRINCIPAL WORKINGS ALONG THE LINE OF LODE.

Last month we quoted the report by A. G. Burrows and P. E. Hopkins on the Kirkland Lake district, made for the Ontario Department of Mines, reproducing that part of the report dealing with the general geology and the ore deposits. Herewith we give their account of the development work done at each mine.

Elliott Kirkland.—This property lies to the west of the Kirkland Lake mine. It includes three claims, on the principal of which the shaft and mine buildings are located. The main fracture zone has been traced westerly through low land from the Kirkland Lake mine. A vertical shaft has been sunk 537 ft., with cross-cuts on five levels and drifts on the third, fourth, and fifth levels along fault planes. The rocks encountered are porphyry, lamprophyre, syenite, and reddish felspathic quartzite. During the time of the strike at Kirkland Lake the workings were allowed to fill with water and no further exploratory work has since been done.

Kirkland Lake.—The Kirkland Lake Gold Mining Company is operating the claim formerly known as the McKane, situated one-quarter of a mile south-west of the lake. Native gold had been discovered in the main vein by the early operators, who also sank No. 1 shaft to a moderate depth. The original discovery was made through about 20 ft. of overburden, the strike of the vein having been determined from workings on the Teck-Hughes and other properties. There are two vertical shafts on the property. No. 1 is in the north-east part of the claim near the Orr line and has been sunk to a depth of 700 ft. (April 1, 1920). The mineralization was followed to 104 ft., where the vein left the shaft on the south side. From the different levels cross-cuts were run to the south to intersect the vein. Since the vein dips approximately 85° S., the cross-cuts are slightly longer at each succeeding level. Drifts have been run on seven levels, but those on the first and second are short, the values obtained not having been as good as those from the 300 ft. to the 700 ft.



PLAN OF MINING PROPERTIES AT KIRKLAND LAKE.

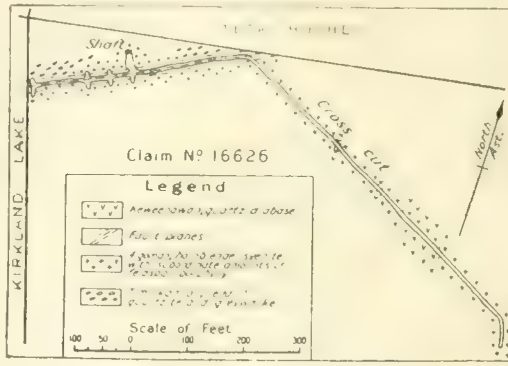
levels. A main hoisting shaft is 600 ft. south-west from No. 1 shaft and to the south of the main vein as exposed on the surface. This contains two hoisting compartments and a manway compartment, and is connected on the third, fourth, and fifth levels with the main workings along No. 1 vein. With depth the connecting cross-cuts become shorter owing to the dip of the vein to the south.

The main vein is recognized by the presence of fault planes, which dip to the south. These are called the foot-wall and hanging-wall planes, and they vary considerably in distance apart in different sections of the mine. At the cross-cuts from No. 1 shaft on the 400 ft., 500 ft., 600 ft., and 700 ft. levels they are respectively 19 ft., 33 ft., 40 ft., and 40 ft. apart. The area between the principal faults is very much disturbed, since minor

fault planes and cross slips have in part controlled the ore deposition. Exploration has shown that there is consequently great irregularity in the mineralization in the fractured zone and values change quite rapidly in driving along the vein. The development has been carried on with regard to the two principal planes or vein boundaries. On the 400 ft. and 500 ft. levels drifts have been run on the foot-wall and hanging-wall sides of the vein for some distance, and up to the present time the greatest amount of development has been done on these levels, where large stopes have been opened up, that on the 400 ft. level being about 300 ft in length and 23 ft. wide at one point. The assay-plans of the stopes have shown the greatest values to be in the foot-wall section of the vein. Development has also shown that the ore sometimes extends beyond the recognized vein boundary planes. The best grade of ore has been obtained where the fault planes or vein boundaries are moderate distances apart, roughly 15 ft to 25 ft. Where they are within a few feet of each other the values are not so good, and where very widely apart the values have a tendency to become more scattered. The ground between the fault planes is so broken and contains so many slip planes that it has been found advisable to leave solid backs above the drifts to protect them from the weight of broken ore in the stopes.

The development has so far indicated that the principal ore shoot extends from above the 300 ft. level to below the 700 ft. level, the deepest workings up to this time The ore-shoot pitches somewhat to the west, but sufficient development has not been accomplished to delimit its actual outline. On the third, fourth, and fifth levels the ore-shoot extends easterly to the Orr west boundary Some gold values are generally obtained along the main vein fracture, but these are not always of commercial importance. However, this mineralization indicates the possibility of exploration developing other ore-shoots. A heavy fault plane is often in evidence in the workings, the gouge being frequently several inches thick. Considerable brecciation of ore has occurred, indicating faulting subsequent to ore deposition. The best ore is a bright red porphyry or syenite through which there are ribbons of quartz carrying tellurides, copper pyrites, iron pyrites, molybdenite, graphite, calcite, and native gold. The vein is principally in the porphyry and syenite that lies adjacent to a band of conglomerate, greywacké, and quartzite, in which the shaft has been sunk entirely from above the 300 ft. level to the 700 ft. level. The dip of the contact is approximately the same as that of the vein, or about 85° S. The north fault plane or foot-wall of the vein is sometimes in the sedimentary formation. High-grade ore with visible gold was observed on the 400 ft. and 500 ft. level stopes, which, together with a lower grade, is expected to average approximately $10 a ton. The ore is hoisted in the main shaft, passed through a crusher, and carried to the mill bin on a conveyor belt. The mill treats 140 tons per day and the recovery is 92 to 95 per cent.

Orr.—The main fracture of the area passes from the Kirkland Lake mine across the north-west corner of the Orr claim, otherwise known as the Orr-Wettlaufer, and extends to the Teck-Hughes and Lake Shore on the north-east. The vein on the Orr property was discovered in 1913 and some work done. In 1917 the property was optioned to the Kirkland Porphyry, and considerable underground work was done. Ore was developed on the 280 ft. and 400 ft. levels during 1918. In 1919 a long cross-cut, 700 ft. in length, was driven on the 400 ft. level to the south-east to reach a parallel vein that outcrops 575 ft. to the south. The cross-cut was thought to be within a few feet of the objective in June, 1919, when the miners went on strike and all work was suspended. The main No. 1 vein, on which some ore has been developed, is approximately 300 ft. in length on the surface and 400 ft. on the fourth level, the gain in length being due to the vein dipping approximately 83° to the south. A vertical shaft has been sunk to a depth of 420 ft. On the 150 ft., 240 ft., 280 ft., and 400 ft. levels the vein has been cross-cut at 12 ft., 18 ft., 23 ft., and 50 ft. respectively, to the south of the shaft. The vein is similar in character and structure to the main vein on the adjoining properties. For a depth of about 300 ft. the vein is on or near the contact between the sediments and a red hornblende syenite. The shaft at a depth of 310 ft. passed from conglomerate into syenite. On the 400 ft. level the vein in places is entirely in the syenite, while in the west work-

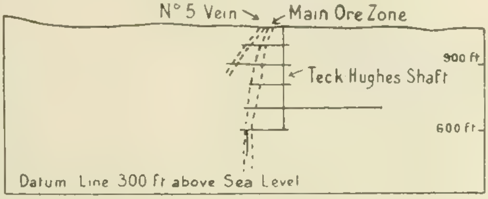


Plan of Orr Mine at 400 ft. Level

ings it is in the contact between quartzite and syenite. There are two main faults from 12 ft. to 25 ft. apart, along and between which the ore occurs. A central fault is also quite pronounced, and there are numerous minor slips. A narrow drift 400 ft. in length has been driven along the central fault in ore. Several cross-cuts on this level show that there is high-grade across narrow widths on both the hanging wall and foot-wall. The high-grade is comprised of silicified porphyry with numerous molybdenite streaks and much iron pyrites, chalcopyrite, altaite, and gold.

Teck-Hughes.—The main ore-bearing zone of the Kirkland Lake area passes through a southern portion of the Teck-Hughes property, where it is known as vein No. 3. The bulk of the gold produced at the mine, namely $316,882 up to the end of 1919, has come from this vein. It occurs largely in the porphyry and syenite, but passes for several hundred feet along the contact between the intrusives and the conglomerate. Practically all the early development work in 1913 was done on vein No. 1, which lies about 100 ft. north of the main zone. The main vertical No. 1 shaft at the east side of the property was commenced on vein No. 1, which dips 80° to the south. The vein is composed of brecciated porphyry and quartz from 2 ft. to 6 ft. wide and carries low contents of gold. Shafts Nos 2 and 4 are to the west on a narrow vein in the conglomerate which may be a continuation of the No. 1 vein. This vein resembles the vein in the conglomerate on the Ontario-Kirkland. No. 3 shaft near the south boundary of the claim has been sunk 200 ft. on the main ore deposit with winzes down on ore to the fourth level. Cross-cuts from the No. 1 shaft have cut the main No. 3 ore zone at distances ranging from

100 ft. to 170 ft. to the south. Drifts, each approximately 1,000 ft. long, extend along the main zone on the second, fourth, and fifth levels. A cross-cut to the vein has been made on the sixth level. Over 10,000 ft. of underground work has been accomplished to date above the 600 ft. level. The section shows the workings and ore-shoots on the main vein, as recognized up to March, 1920. Vein No. 5 is a branch from the hanging-wall side of the main vein and dips about 60° to the south. The ore in the main No. 3 vein, which is typical of the ore described on other properties, occurs in shoots usually between two prominent, nearly parallel mud seams or faults, from 6 to 40 ft. apart, and dips 85° to the south. The faults or slips are often filled with gouge from an inch to six inches in thickness, narrowing down in places to mere cracks. In many places secondary minerals such as quartz, calcite, and reddish barite fill the faults. The ore, which is similar to that on the adjoining properties, is comprised of brecciated syenite, porphyry, and quartz cut by veinlets of quartz, the whole containing numerous slip planes. The minerals present are pyrite, copper pyrites, molybdenite, altaite, and gold.



CROSS SECTION OF TECK-HUGHES.

The ore-shoots are irregularly distributed throughout the faulted zone. Usually the shoots lie on the inside and adjacent to one of the main fault walls. In places, however, the ore is continuous between the two fault walls, while in other places the ore extends out beyond a fault wall. Two or three main faults are apparently subsequent to the ore deposition, but act as guides in following the ore. The shoots range in size from a few feet to over several hundred feet in length, being at times over 40 ft. in width. It has been found that the best ore usually occurs where the faults are a considerable distance apart, or where there is a sharp roll in the dip along the main faults. The south or hanging wall has produced more ore than the foot-wall. The values are so erratic that the careful sampling of every face or round is required to locate the ore-shoots. Stoping, however, has shown that the values are not so uneven as lateral work would indicate. In 1917-18 the ore averaged $7·87 per ton, which was a lower value than was indicated by the underground sampling. This was due to a dilution with waste rock caused by the easy breaking qualities along numerous slips in stoping. Ore, however, occasionally extends behind one of the fault planes or the supposed ore wall, hence horizontal drill-holes are put in at regular intervals beyond the supposed ore wall for testing purposes. The west shoot was found to extend from the surface to the fifth level and to be still continuing as shown on the section. The values in the large stope above the 400 ft level near the eastern boundary of the property were more even than in the other ore-shoots. The fractured zone between the ore-shoots assays from 40 cents to $4 00 in gold, per ton ; hence the grade of ore varies according to the amount of lower-grade material that is mined with the higher-grade.

Lake Shore. — The Lake Shore Mines property is a consolidation of five claims along the main fracture zone that passes through Kirkland Lake. It includes an area on the south side of the lake and also the southerly part of the lake bed itself. The first work was done on No. 1 vein on the south shore of the lake, where a vertical shaft has been sunk to a depth of 400 ft. and drifts run on the 100 ft., 200 ft., 300 ft., and 400 ft. levels, the greatest amount of work having so far been done on the third and fourth levels. Development has shown that the vein dips slightly to the north above the 200 ft. level. A strong fault was encountered just above the 200 ft. level, dipping 25° to the south. The fault displaced the vein a distance of 28 ft. From the 200 ft. level to the 400 ft. level the vein is nearly vertical. The 400 ft. level is also connected with the surface by rises. With the exception of a small amount of ore from back-stoping and rises, all the ore obtained from No. 1 vein has so far been taken from the drifts. The ore occurs chiefly in the reddish porphyry, but parts of the vein have conglomerate and lamprophyre as wall-rocks. Owing to the small amount of cross-cutting the distribution of these bands of other rocks has not been worked out.

On the 200 ft level, 100 ft. west of the shaft, lamprophyre has been faulted over porphyry. A strong cross fault, 310 ft. west of the shaft, on the 400 ft. level, striking nearly north and south and dipping nearly vertically, has displaced the part of the vein lying to the west of the fault 20 ft. to the south. This fault is also indicated in the workings in the west drifts on No. 2 vein. The work on the vein in the vicinity of this fault was rendered difficult by the occurrence of several subsidiary faults.

Cross-cuts have been run from the shaft northwesterly on the 200 ft. and 400 ft. levels to intersect No. 2 vein under the bed of Kirkland Lake. This vein is on the main fracture that is being developed at a number of mines over a distance of 2¼ miles. It has

been driven on north-easterly and south-westerly from the cross-cut on each level, the greatest amount of driving having been done on the 200 ft. level. Here the vein is opened up for a distance of 1,500 ft., for the greater part in ore. With the exception of some back-stoping, preparatory to timbering for mining, the ore extracted has come from development. Red felspar-porphyry and syenite occur with the vein over most of the distance so far developed, but in the west drift, 330 ft. from the cross-cut, this rock is associated with bands of conglomerate and lamprophyre to the face of the west drift (April 15, 1920), about 800 ft. from the cross-cut. The west face is entirely conglomerate, and for a distance of about 150 ft. the vein is in this rock and is of commercial grade. Ore also occurs where lamprophyre is the wall-rock. Development on the 400 ft. level is similar to that on the 200 ft. level, the vein where opened being principally in the red porphyry and syenite with conglomerate showing in the west drift. A long stope has been opened on this level and at the time of visit was almost through to the 200 ft. level. Fracture planes occur along the vein, the ore-body showing slickensided, nearly vertical walls with a slight dip to the south. The ore is largely of the red porphyry type, associated with which is quartz in lenticular masses and ribbon-like structures. Brecciation of the ore is evident in the fractured character of the porphyry and the vein quartz. Minor slip planes occur along the ore-body, and commercial values sometimes cease at one of these slips and come in again on other slips in driving along the vein. Constant assaying of faces is necessary, since the ore sometimes turns off, from where it has been following a well defined wall, diagonally along another wall. In addition to the fracture planes with which the ore is associated there are heavy faults showing much clay gouge in places that in part have followed the ore-bodies, and again are not near the ore-body. One of these faults was driven on for 210 ft. easterly from the cross cut on the 200 ft. level, being mistaken for the vein. Later it was discovered that the ore-body had turned off from this heavy fault 40 ft. from the cross-cut on the north side. Beyond this it was followed north-easterly for several hundred feet nearly to the Wright-Hargreaves boundary. The ore-bodies vary in width, and it is difficult to determine the widths along the drifts, which are usually about 5 ft. wide, and frequently all in ore. Much of the ore in the 400 ft. stope on No. 2 vein will average 11 ft. in width. In mining in the stopes the walls are tested by horizontal drill-holes at regular intervals and the stoping continued to the boundary of the ore.

Wright - Hargreaves.—The Wright - Hargreaves mine is situated on the main ore-bearing fracture near the centre of the productive area, where the porphyry rocks have the greatest exposed width in the area. The mineralized zone has been traced intermittently for 2,400 ft. on the surface, and it undoubtedly extends for 1,500 ft. across the western part of the property, which is covered by a portion of Kirkland Lake and passes to the Lake Shore mine on the west. The zone is roughly parallel to the longer boundaries of the property. It was in veinlets in this fracture that gold was first found in the area in 1911 by W. H. Wright. During that autumn two core-drill holes were put down on the vein with a shot-drill. The holes were driven only to shallow depths, partly on account of the hardness of the porphyry. Cartwright took an option on the property, and in 1913 discovered a small rich vein about 550 ft. north of and parallel to the main vein. A 60 ft. shaft was sunk on this vein, which is 5 ft. or 6 ft. wide, and also in the porphyry, from which 3·4 tons of ore was shipped giving returns of $331 to the ton. The option was allowed to lapse, and the property lay idle for a long time before the present Wright-Hargreaves company commenced operating. Two shafts about 950 ft. apart have been sunk on the main fracture to the 300 ft. and 400 ft. levels respectively, and a drift on the 300 ft. level to connect these shafts is about half completed. The vein and ore are very similar to those of the Lake Shore. The vein varies in width from a few feet to over twenty feet. The north, or No. 2 vein, is similar in appearance to the main vein. The strike of the western portion of the vein suggests that it may be a branch from the main vein. This No. 2 vein where located at the 300 ft. level by a long cross-cut from the main shaft was reported to contain high-grade ore over a stoping width. The vein at this point occurs slightly to the north of the vertical projection of the 60 ft. shaft, which would indicate that the vein either dips to the north or has been faulted in that direction. The underground workings of this mine were filled with water at the time of inspection, but the owners state that ore of good grade occurs in a number of faces. Sufficient work has not been done to show the sizes and number of ore-shoots. However, the property gives promise of becoming a substantial producer. A 175 ton mill was commenced in the spring of 1919, but owing to the miners' strike during that summer all work was suspended until May, 1920.

Tough-Oakes.—The property was the first to be operated in the area following the discovery, in January, 1912, of gold-bearing veins in the porphyry and conglomerate. It consists of five claims situated along the boundary lines between Teck and Lebel townships. Surface prospecting in the early years of the mine resulted in the finding of 11 veins in the porphyry, greywacké, and conglomerate, some of the veins passing from one to the other formation. The veins are roughly parallel with the average strike, somewhat south of west. The principal development has been on veins Nos. 2, 3, and 6, the first two producing most of the ore already taken from the mine. The veins were traced on the surface by trenching. No. 2 vein was traced for 370 ft.; No. 3 for 830 ft.; No. 6 for 1,460 ft., entirely in porphyry, with 740 ft. of it showing an assay-value of about $12 per ton for a width of 60 in.; No. 7 was trenched for 245 ft. in the greywacké, the quartz rib of which averaged 18 in. with stringers in both walls. In the first three years of operations high-grade ore was hand-sorted and shipped to smelters. The richness of the ore can be judged from shipments. In 1912 and 1913, 101 tons with a value of $46,221, or $457 per ton, were shipped to smelters. In 1914, 212 tons, with a value of $781,590·38, or $350 per ton, were shipped. After being hand-sorted the remaining ore was treated in a 5-stamp mill by amalgamation, with a recovery of 55%. The tailings from this treatment were impounded, and later treated in the new 100 ton cyanide plant in operation in March, 1915. The operations of the small stamp-mill may be judged from the statement that during 1914 there were treated 3,493 tons of ore with a head value of $22·35 per ton for a recovery of $43,353. The ore raised from the mine in 1914 had an average value of $41·18 per ton.

The veins that were developed were comparatively narrow, and the average stoping width was about 5 ft. An idea of the value of the ore along drifts is obtained from statements in annual reports of the company. For instance, in No. 2 vein one section of ore on the 200 ft. level had an assay-value of $78 for a length of 218 ft. and width of 65 in. A section on the same vein on the 300 ft. level showed an assay-value of $32 over 65 in.; 180 ft. of driving on vein No. 3 on the 200 ft.

THE LAKE SHORE MILL

level had an assay-value of $32 over a stoping width of 63 in. The early development was on No. 2 vein, the first work being an open-cut, from which the first shipments of high-grade ore to smelters were made. An incline shaft (A) was then sunk on the vein, which has a dip of 55° south, and the main ore-shoot developed on four levels. The workings that started in conglomerate passed into porphyry and the high-grade character of the ore was maintained. In driving westward on different levels the vein was found to be faulted by a basic dyke a few feet in width that strikes N. 20° W., and dips nearly vertically. Within the dyke there are heavy fault planes. The dyke was encountered 295 ft. west of the shaft on the 200 ft. level. The extension of the vein on the west side of the fault has not been determined definitely; one theory is that No. 1 vein, exposed on the surface 340 ft. south of No. 2 vein, is the faulted portion of No. 2 vein. High-grade ore in No. 2 vein was cut off abruptly against the dyke, and consequently the solving of the fault problem is of great importance to the mine. The dyke is known to have displayed a strong east and west fault, dipping 87° S. on the Burnside to the south, a distance of only about 8 ft. horizontally; while No. 11 vein, with a dip of 80° S. on the Tough-Oakes 180 ft. north of No. 2, has been apparently faulted only very slightly. In view of these facts it is probable that the displacement has been largely in a vertical direction. The main ore-shoot on No. 2 vein has a stope length of about 250 ft. on the 300 ft. level. The easterly margin of the ore-shoots indicates a pitch to the west. Ore-shoots were also developed on subsidiary veins to No. 2. Shaft B was sunk on No. 3 vein, which also dips to the south, and development continued below the 100 ft. level by means of a number of winzes to the 400 ft. level. The main ore-shoot on No. 3 vein also pitches to the west. No. 6 vein and other parallel veins near No. 3 vein were also opened from the workings at B shaft. The workings on No. 3 and parallel veins are connected with A shaft on No. 2 vein by a long cross-cut on the 200 ft. level. The ore from different parts of the mine is hoisted through the A shaft. Since the amalgamation of the Burnside with the Tough-Oakes, No. 2 shaft (vertical) on the Burnside has been deepened and connected with A shaft on the 400 ft. level by a long cross-cut. This shaft will be used for handling men and supplies. C shaft, sunk to the 100 ft. level on vein No. 1, and shaft No. 3 on the Burnside are not as yet connected with the main workings of the Tough-Oakes.

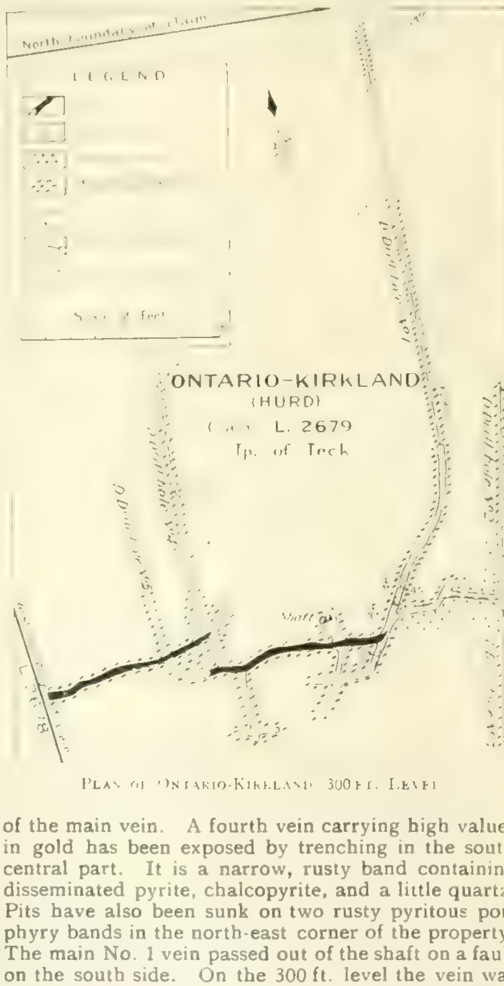
PART OF THE TOUGH-OAKES PROPERTY

Sylvanite.—This property lies between the Wright Hargreaves and Tough Oakes mines with workings in the felspar porphyry along fracture zones. The property was not in operation in 1919, but during 1917 a shaft was sunk to a depth of 120 ft. and 169 ft. of cross cutting and driving was done on the 100 ft. level. The mineralization as exposed where the vein is stripped on the surface is similar to other occurrences, where altered porphyry with quartz veinlets form the ore.

Kirkland Combined.—The Kirkland Combined Mines is operating the Day Claims which adjoin the Sylvanite on the north, and corner the Tough-Oakes on the north-west. These two claims were formerly known as the Wishman claims, and considerable trenching and surface sampling were done in 1913. The claims, which were allowed to revert to the Crown, were restaked and operated in the autumn of 1919 by the Kirkland Combined Mines. Air was delivered from the electrically driven compressor on the Sylvanite. The west claim is practically all lamprophyre, while the east claim, on which most of the work has been done, has about equal proportions of conglomerate, lamprophyre, and porphyry. Extending along the porphyry-lamprophyre contact and passing into the lamprophyre to the west is a pronounced fracture zone, which is 5 ft. wide and traceable on the surface for over 500 ft. in an east-west direction. Veinlets of quartz and considerable iron pyrites and some molybdenite occur in the fault zone. Samples yielding low gold contents on assay have been obtained from a few places in the vein. By diamond-drilling it was found that the fracture zone was mineralized with pyrite to a depth of about 200 ft. At a point on the surface where the vein passes from the lamprophyre into the porphyry-lamprophyre contact a vertical shaft was sunk to a depth of 200 ft. and a 106 ft. cross-cut driven to the south. The vein passes out of the shaft on the south wall at a depth of 85 ft. In the cross-cut on the 200 ft. level two nearly parallel mineralized fractures were encountered, 20 ft. and 40 ft. respectively south of the shaft upon which driving is being done, the south fracture being on the porphyry-lamprophyre contact.

Black.—The Black claim lies immediately south of the Wright-Hargreaves east claim. Near the north boundary is a vein striking north-east in the conglomerate, on which a shaft has been sunk to a depth of 155 ft. No mining was being done in the summer of 1919, but the vein, which is mineralized conglomerate with quartz stringers, is lenticular and narrow. It is said to contain in places high-grade ore over a width of 4 or 5 inches.

Ontario-Kirkland.—The Ontario-Kirkland Gold Mines owns two claims, formerly known as the Hurd, which are situated about three-quarters of a mile south of the central ore zone of the Wright-Hargreaves. These claims were optioned during the early part of 1917 to the La Rose Mines, who stripped and sampled a part of the surface and sank a 100 ft. shaft on the main vein, after which the option was dropped. The present company continued the shaft to a depth of 300 ft., where 1,000 ft. of driving and cross-cutting and 930 ft. of horizontal diamond-drilling have been done, resulting in the finding of some ore. Recently (May 23, 1920) the shaft reached the 450 ft. level, where two gold-bearing veins were encountered at points 25 ft and 37 ft. respectively south of the shaft, and upon which additional lateral work is being done. The rocks consist of schistose conglomerate and greywacké, which have been intruded by typical reddish felspar-porphyry. The largest porphyry mass in the area extends across the northern part of the property. It is 250 ft. wide on the surface and one-half that width where it has been pierced by a diamond-drill hole on the 300 ft. level. The porphyry in the south-west part is unusually schistose. Six veins have been found on the surface, all of which are practically vertical, with a nearly east-west strike. They occur largely in the sediments. Two extend from the conglomerate into the porphyry, while another is entirely in the porphyry. The main No. 1 vein, on which most work has been done, has been traced for 400 ft., the western part in a yellowish sediment resembling altered porphyry schist. At the shaft the vein passes into conglomerate, and farther east it has been faulted and probably extends into the porphyry. Two narrow short veins occur about 60 ft. and 80 ft. respectively to the south



PLAN OF ONTARIO-KIRKLAND 300 FT. LEVEL

of the main vein. A fourth vein carrying high values in gold has been exposed by trenching in the south central part. It is a narrow, rusty band containing disseminated pyrite, chalcopyrite, and a little quartz. Pits have also been sunk on two rusty pyritous porphyry bands in the north-east corner of the property. The main No. 1 vein passed out of the shaft on a fault on the south side. On the 300 ft. level the vein was located at a point 25 ft to the south of the shaft, and driven on for 180 ft., over which length the values were reported by the manager to average $12 in gold per ton across 5 ft. The deposit consists of altered conglomerate and greywacké, quartz veinlets, iron pyrites, copper pyrites, and some molybdenite. Little gold is visible. The ore has been cut off at both ends by faults. The portion of the vein to the east of the fault has not been definitely located, but a mineralized porphyry fault zone in the north-east cross-cut may be this extension. To the west of the west fault a some-

what similar ore deposit, but not necessarily the continuation of the No. 1 shoot, has been located 35 ft. to the north. A drift on this deposit for a length of 150 ft. was reported to average $17 per ton across 6 ft.

Montreal-Kirkland. — These claims are situated south of the Ontario-Kirkland. A shaft has been sunk on claim number L. 6681, but was full of water at the time of inspection.

Hunton.—The Hunton property is situated nearly a mile south of the south-west end of Kirkland Lake and consists of two claims. A porphyry dyke with strike N. 66° E. intrudes the schistose sedimentary rock near the line between the claims; most work has been done so far on the northerly claim. A mineralization occurs along the south contact, extending into both formations. An open-cut was made along a series of narrow quartz veinlets 1 in. to 3 in. wide, which intersect the sediments and porphyry, the cut passing from the sediments to the porphyry to the north-east. A shaft was sunk to a depth of 40 ft. in the sediment with the porphyry on the north wall. The mineralization is reported to extend to the bottom of the shaft, while visible gold was encountered down to about 30 ft. Diamond-drilling indicated gold in the core from a depth of 254 ft. from the surface, vertically. By open-cuts and pits the mineralization has been traced for 300 ft. along the surface. Just north-east of the shaft three quartz stringers dipping south are exposed in the open-cut; while 25 ft. from the shaft there is a quartz vein 2 in. wide running diagonally across the trench, N. 30° E. in the porphyry, carrying extremely rich showings of gold with pyrite. The gold is very fine, almost like mustard gold, and shows as a yellow stain throughout the quartz. The porphyry and quartz along the rich streak carry abundant iron pyrites. This mineralization is adjacent to a fault plane that strikes in the same direction as the vein.

Chaput-Hughes.—A power plant has been installed on this property and a shaft has been commenced.

Honer.—This property is just west of the Hunton. The rocks are sediments intruded by narrow dykes of red porphyry striking north-east and south-west. Several quartz veins have been found, the principal one of which is in the south-west part of the claim. It has been traced about 300 ft. and prospected by means of several pits and a shallow prospect shaft. It occurs in schistose sediment on the north-west side of a porphyry dyke. Where seen in one pit the structure shows a somewhat banded character of quartz veinlets in the sediment over a width of 6 ft., with the wider quartz bands toward the centre of the deposit. The quartz veins dip 70° to 80° S.E., and the best values are reported to occur in the foot-wall side in the narrow seams of quartz. The principal metallic sulphide is iron pyrites. A working shaft was being sunk near the north-east end of the exposure of the vein.

Canadian Kirkland.—The property is situated a few hundred feet south of the Swastika-Kirkland Lake road, 1¼ mile south-west of Kirkland Lake. The surface exposures are schistose sediments, conglomerate, greywacké, and slate, intruded by narrow dykes of red felspar-porphyry and a younger diabase dyke that runs south-west through the property. There is a thin mantle of drift on much of the surface, requiring trenching to expose the rocks. Two vertical shafts and several pits have been sunk on mineralized zones. The main shaft was sunk on a mineralized zone in the greywacké, consisting of quartz veinlets and greywacké impregnated with iron pyrites, copper pyrites, galena, and calcite. The strike of the mineralized zone is E.N.E. and W.S.W. A section exposed in the shaft shows a series of quartz veinlets about one inch wide, dipping steeply to the south across the shaft to the 150 ft. level. A short cross-cut was made southward at the 100 ft. level, and on the 150 ft. level a cross-cut was made to the north and south of the shaft. Promising assays were obtained for about 85 ft. in the shaft, but no driving was done to determine whether the mineralized zone pitched eastward or westward. The cross-cut at the 150 ft. level is in greywacké with fine-grained slate-like rocks 85 ft. south of the shaft.

THE NEW CITY DEEP SHAFT.

At the meeting of the Institution of Mining and Metallurgy held on February 17, a paper by E. H. Clifford was presented describing the City Deep South Shaft which is being sunk to a depth of 7,000 ft. in order to work the deepest parts of the gold-bearing reef on this property.

The claims of the City Deep cover an approximately rectangular area 2·3 miles along the strike by 1·2 on the dip. The Main Reef Leader, which is virtually the only reef worked, lies at a depth of about 2,000 ft. at the top or northern boundary, and at the southern boundary its depth probably ranges between 6,600 ft. and 7,300 ft. The mean dip is rather less than 40°. The mine is now being operated from two vertical rectangular seven-compartment shafts, 4,000 ft. apart, having depths of 3,300 ft. and 4,000 ft. respectively. From the bottom of these shafts there extend two five-compartment inclines which underlie the reef and are connected with it by cross-cuts at each level. The inclines have two double hoisting ways and a ladder and pipe compartment. The West Shaft has reached the 20th level and the East the 18th level; the vertical depth of the 20th level being 4,950 ft. In addition, there is a ventilating shaft 2,200 ft. deep near the northern boundary. The monthly output is about 80,000 tons. While incline shafts of short length and in firm ground are an excellent means of opening a mineral deposit inclined at a dip less than 45°, it is found in practice that they become unsatisfactory under opposite conditions. On account of the difficulty of filling very large skips, it is not possible to increase loads indefinitely, nor is it possible to reach the winding speeds that are common in vertical shafts, consequently the shaft capacity falls away very rapidly when a certain length is reached, usually about 3,500 ft. Furthermore, inclines are difficult to manage, and expensive to sink and maintain, in bad ground or where the pressure becomes heavy, and obviously this difficulty is most serious where the span is large. The City Deep inclines will before long not only have reached the vertical depths at which troubles with rock pressure are likely to become serious, but at the same time their length will also have reached the economic limit. In this instance, the latter will be about the 22nd level, at a vertical depth approximately 5,300 ft. below the surface. There will remain, therefore, an area equal to about one-third of the property which is not provided for by present appliances, and the problem was how to exploit it. Briefly, the scheme adopted consists in sinking a vertical shaft of circular section 7,000 ft. in depth, in two stages of 4,500 ft. and 2,500 ft. respectively. The upper section will stop at the 17th level, where it will make connection with the two incline shafts, and the reef will be attacked from the lower section of the shaft by cross-cuts at each level.

The capacity required of the shaft is 2,000 tons of ore per 24 hours plus all the men, natives, and materials

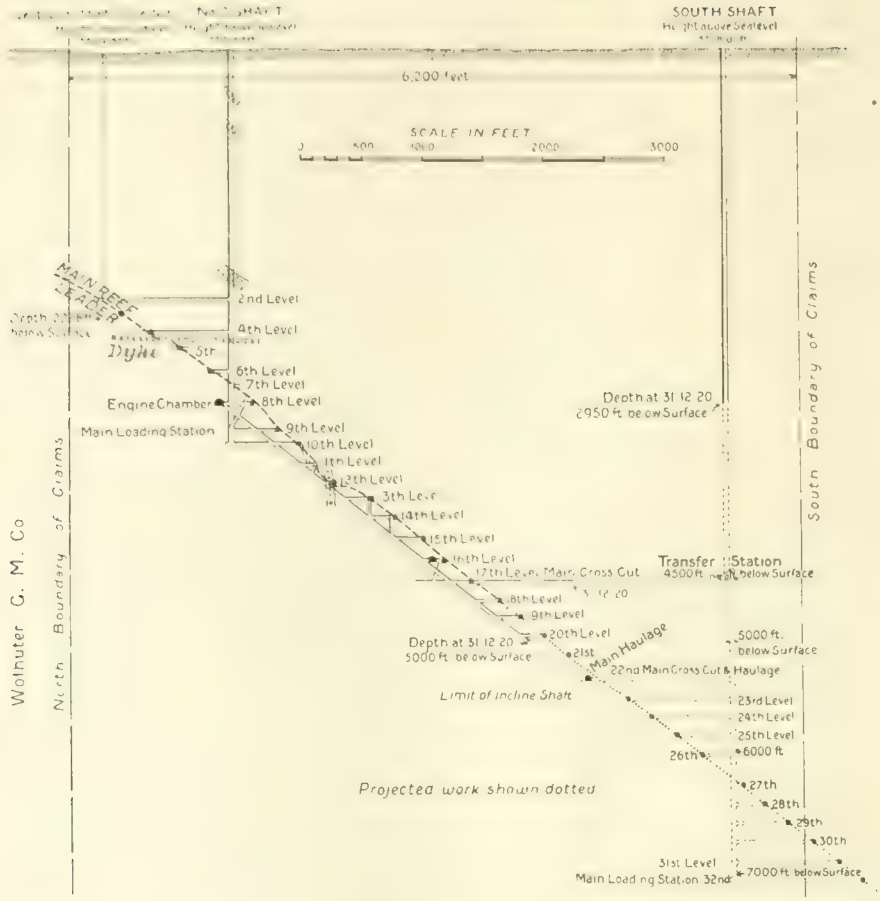


FIG. 1. VERTICAL SECTION OF CITY DEEP SHOWING POSITION OF NEW SHAFT.

necessary for this output, together with a liberal allowance for contingencies. In addition to this the shaft must be capable of carrying 300,000 cu. ft. of air per minute, without undue consumption of power. It may be questioned whether it would not have been preferable to divide the distance into two equal portions of 3,500 ft. each, thus requiring a moderately large winder on the surface instead of a very large one. The reply is, that the heat released by an electric winder located underground is a serious matter, therefore the smaller it can be made the better. The total heat produced is equivalent to the difference between the total electrical input less the net work of raising the rock, and with the size of winder required for a depth of 2,500 ft. the loss would be about 18,000 B.T.U. per minute while the winder is at work. This considerable quantity of heat can only be got rid of by conveying it to the air, and as it is most desirable that it should be kept away from the lowest workings of the mine, some 75,000 cu. ft. of air per minute must pass through the engine and converter set chamber and along the 17th level cross-cut. In regard to the hoisting of the ore, the work is well within the capacity of one engine, and in view of the enormous cost of large electric winders at the present time, to say nothing of operating costs and duplication of shaft equipment, it is obvious that this is an important consideration. Using a single engine, however, necessitates an alternative route both for men and materials, and this is provided for by means of the 17th level cross-cut which is directly connected with the western incline shaft, and also by means of a main transport drive, with the eastern or No. 1 incline. The transport drive is some distance below the reef and therefore out of harm's way when the stopes cave, and both it and the cross-cut will be equipped with an overhead electric locomotive system. It will thus be possible to bring any ore in the mine to the 17th level, whence it can be diverted to either of the two present winding shafts or to the new main shaft. This elasticity, which is almost complete, is an extremely desirable condition and worth a great deal of trouble to attain. It safeguards the continuity of the mine output in case of accident to any of the shafts and renders possible the laying-off of either of the old main shafts when the output of ore in its neighbourhood becomes too small to keep it busily employed.

The shaft is 20 ft. in diameter in the clear and is fitted with concrete rings spaced at 10 ft. vertical intervals, each ring being 18 in. deep by 15 in. wide. The function of the rings is to provide adequate fastenings for the shaft guides, pipes, cable, etc., and also to afford a foundation for any kind of lining, such as bricks or monolithic concrete, should such lining be found necessary. In this particular case 22 sections near the surface were

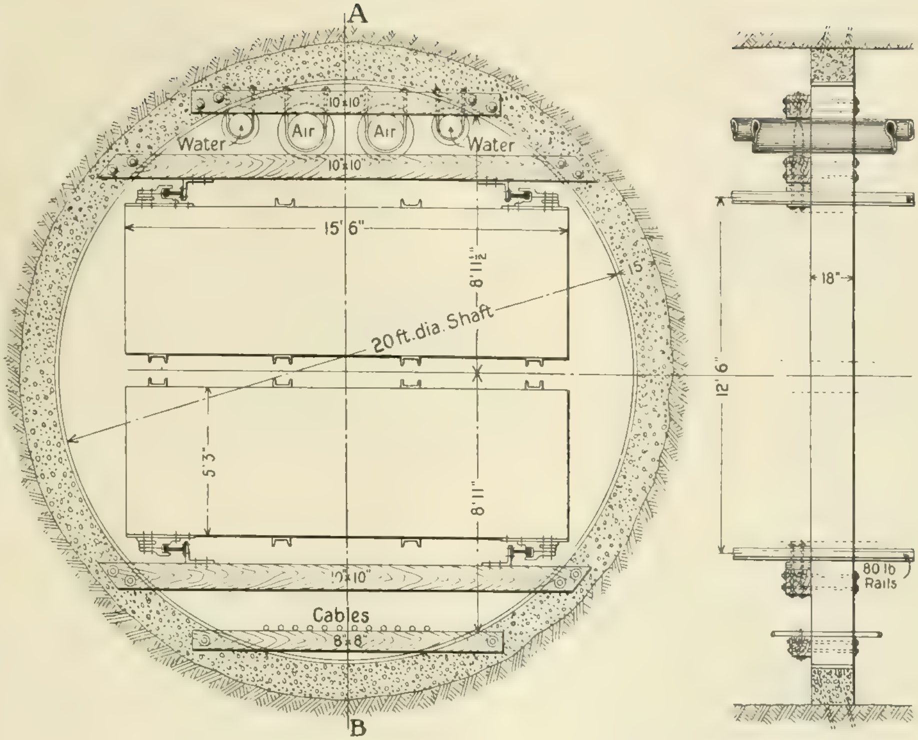

FIG. 2. CROSS-SECTIONS OF THE CITY DEEP SHAFT.

so lined, but the remainder of the shaft as far as it has gone at present needs no support, although it is quite possible that signs of local deterioration may show themselves subsequently, in which case the remedy will be simple. The rocks of the Witwatersrand System are, for the most part, extremely strong and rarely need support, at least in a vertical shaft. The concrete forming the rings is moulded round steel pegs about 20 in number and 24 in. long, driven into drill-holes in the rock. The guides are 80 lb. standard section flat bottom steel rails specially strengthened and fastened to 10 in. by 10 in. pitch pine dividers connected by special fish-plates machined to ensure accurate registration at the joints. It will be observed that the base of the guide rails is at right angles to the divider and not bolted to it directly. The latter method, which results in the heads of the rails facing outward, commonly referred to as the Briart system, necessitates the use of a guide shoe embracing the head of the rail, obviously requiring great accuracy of gauge. This accuracy is not easy to achieve during installation, and still less easy to maintain. The method used in this instance, without sacrificing strength or safety, admits of some latitude in gauge and a simple adjustment for wear. The dividers are placed at the sides instead of one divider in the middle, as the latter scheme necessitates long and rather fragile girders which are bound to be damaged by an accident to either cage, thereby probably putting both cages out of action. Another rather serious objection to a central divider is that it prevents the use of a stage for shaft repairs, an important point in a shaft not provided with ladders. It will be noticed that this form of construction admits of scarcely any timber being used in the shaft equipment, a most important consideration in view of the necessity of keeping the shaft absolutely dry. A timbered shaft should be either wet or dry; if it is damp the timber rots, and if it is alternately wet and dry the shrinkage of the wood leads to continual difficulties in the alignment of the guides. Furthermore, a dry timbered shaft is in perpetual danger of fire. In this instance, wood has not been entirely dispensed with, since, when repairs are necessary, it is a much more convenient material to work with, as anybody who has had experience of an accident to steel-work in a shaft well knows. The position of the guides with relation to the cage is not perhaps ideal; a symmetrical disposition at the centres of the ends would, from this point of view, have been better, but this arrangement would entail the breaking of the guides at landing stations, which is a dangerous practice, and also necessitates short guide shoes which cannot be strongly fastened, instead of the shoes shown, which, if need be, may be made the whole length of the cage.

The concrete rings are moulded in plain steel forms, 20 ft. in diameter, made for convenience in handling in seven sections, which are suspended from the last ring up. The bottom of the form is filled with short lengths of wood to hold the concrete. The filling and removal of the forms is, of course, done from the stage and does not interfere with the sinking. The plumbing arrangements are carefully carried out and consist of a gallery under the collar of the shaft, equipped with four permanent geared winches and $\frac{1}{16}$ in. stranded steel plumb-bob wire. It takes very little time to check the concentricity of the rings and give the sinkers their marks. The lay-out at the transfer station is shown in Fig. 3. By means of hydraulic pushers the cars are transferred from cages to traversers operated from a continuously moving rope by ordinary tramway clips. The track arrangements provide all necessary facilities for trans-

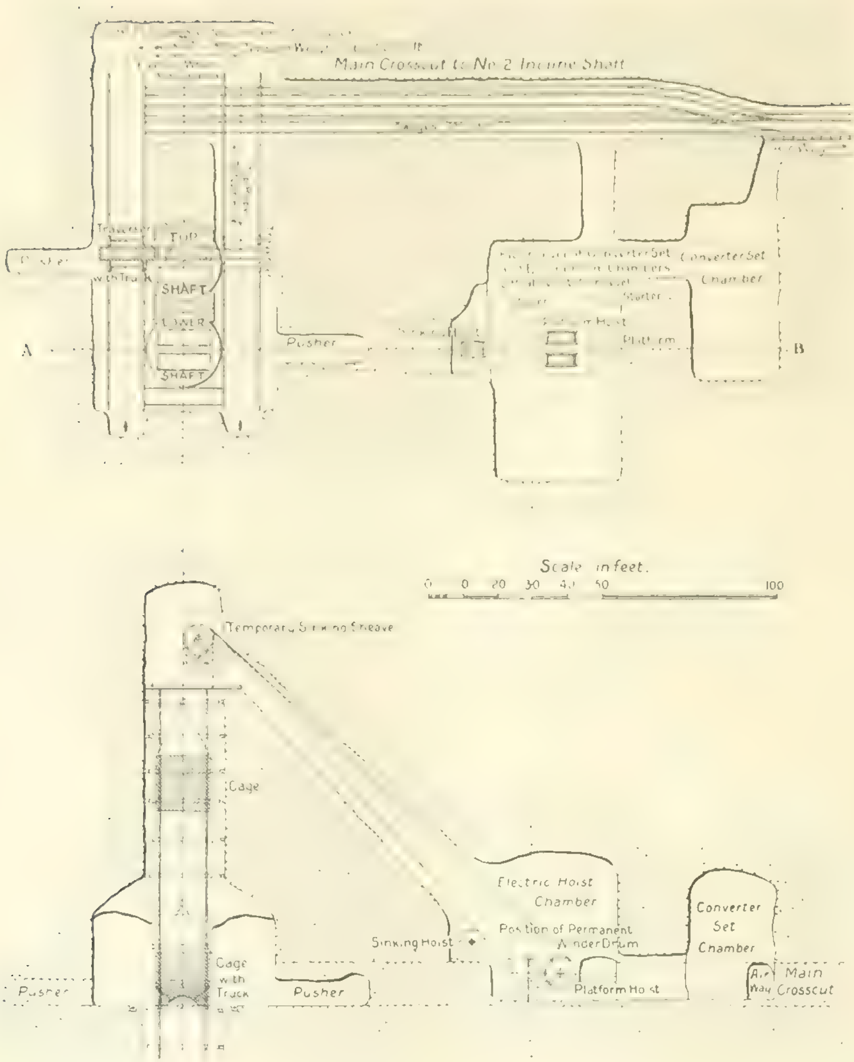

Fig. 3. Plan and Elevation of Internal Hoisting Installation.

ferring cars, both fulls and empties, either direct to the surface or through the cross-cut to No. 2 shaft and vice versa.

The cage is 15 ft. 6 in. by 5 ft. 3 in., with two decks. It is intended to make it of alloy steel, as the saving in weight thereby effected will, in this instance, materially increase the working life of the winding ropes, diminish the consumption of power, and more than compensate for the additional cost. The rock will be carried in a single 8-ton bottom discharge truck in the lower deck, the upper deck being provided for men, the load amounting to 50 on each deck, or 100 in all. The great length of the cage will permit of timber, drill steel, and other stores being taken to their destination in the mine on trucks without any rehandling at the landing stages, an important matter in saving time. The condition determining the size of the equipment is, in this instance, capacity in handling men and material rather than rock-hoisting capacity. The rejection of skip-winding and the adoption of the cage and truck system is a departure from standard practice in this and most other metalliferous districts. The great advantage of skips is, of course, their low tare and ease of loading or unloading. The first advantage is undoubted, but the latter does not show up so well when compared with truck loading into cages by power, especially if the units are large. The disadvantages of skips are, their very low capacity for men and materials, the greater danger of overwinds, and the fact that they do not permit of a large capacity in the headgear ore-bins unless the headgear is built of an inordinate height. The men and material question can be overcome either by duplicating the winding plant or by interchanging cages for skips, but both these remedies are subject to obvious disadvantages. In this

particular instance, skips show still less advantage because at the transfer station on the 17th level it is obviously easier to send ore already in a truck either direct to the surface through the South Shaft or to the other shafts, and vice versa, than it would be to do the same thing if the ore had to be taken from or put into a chute. This could only be done by branch chutes with deflecting doors, which, although satisfactory enough for small tonnages, are a source of continual trouble when the tonnages are large.

THE GREENAWALT SINTERING PROCESS.

In the *Mining and Scientific Press* for January 15, W. E. Greenawalt gives a description of the sintering process and plant invented by J. E. Greenawalt, of 50, East 42nd Street, New York. A number of these plants are in use, the largest, having a capacity of 2,000 tons per day, being employed in sintering magnetite concentrate and flue-dust from iron blast-furnaces respectively. The process, as practically developed, is intermittent in operation. A charge of the material to be sintered is placed in a pan-shaped furnace and subjected to a down-draft blast of air; the upper surface of the charge is ignited and the sintering action proceeds through the charge from the top downward. After sintering, the charge is dumped from the pan and the operation repeated. The apparatus consists essentially of the furnace in which the charge is sintered; an exhauster which creates a blast of air downward through the charge; a mixer; a charge-car; and an igniter. The mixer, the charge-car, and the igniter, may serve from one to ten or more sintering-pans. Mixing is an important preliminary step to sintering. A properly mixed and proportioned charge sinters readily and the resulting sinter is usually in large chunks. A poorly mixed, or poorly proportioned, charge is likely to give inferior results, in which a considerable portion of the charge has to be returned for re-sintering. The charge should have about 10% moisture. The mixing may be done in a rotary drum like a concrete-mixer, in a rotary cylinder, or in a pug-mill. With thorough mixing, the charge becomes uniform in moisture and the combustible content is evenly distributed through the charge. The combustible content of the charge is important. It is impossible to get a good sinter from a concentrated sulphide material, or from iron-ore fine, containing an excessive amount of coke. The sulphur content in sintering lead or copper ores may vary from 5% to 15% sulphur. In sintering iron-ore flue-dust or magnetic concentrate the coke content may vary from 3% to 10% carbon. A good sinter may be made on some charges with as little as 2% carbon. Ordinarily, from 4% to 6% carbon, in the sintering of iron-ore flue-dust, will give the best results. In the sintering of copper-ore fine or flue-dust, from 5% to 10% sulphur will give uniformly good results. In sintering iron-ore fine, low in sulphur, the sulphur can be removed almost entirely. On the other hand, when it is desired to retain a high percentage of sulphur in the sinter, as in sintering copper-ore fine for the blast-furnace, this may be done by stopping the operation after the material has been sintered and before the sulphur is all removed. In cases where the material to be sintered contains too much combustible, such as coke or sulphur, the best method to adjust it is to dilute it with other fine material desired in the blast-furnace charge, such as any fine having a low combustible content. In sintering copper-sulphide concentrate the sulphur content can usually be adjusted to the desired amount by mixing flue-dust or fine crude ore with the sinter charge. In cases where such mixtures cannot well be made, as in galena concentrate, the material may be pre-roasted to bring the sulphur down to about 12% or 15%. Pre-roasted material sinters readily. The moisture in the charge, to get the best results in sintering, may vary somewhat with different material, but 10% moisture will be found a fair average.

The sintering pan consists, essentially, of a pan-shaped sintering-furnace, mounted on hollow trunnions, and divided into an upper and a lower portion by the grates. The upper portion receives the charge for sintering, and the lower portion communicates, through the hollow trunnions, with the exhauster, which creates a suction in the lower portion, or chamber, and causes a flow of air downward through the charge and through the hollow trunnions and exhauster into the stack. The grates are secured to the pan and interlocked. They are easily inserted and easily removed. The pans are made in various sizes. The usual sizes are: 6 by 8 ft., 8 by 12 ft., 9 by 16 ft., and 10 by 24 ft. The depth of the charge is the same for all the pans, and varies from 8 to 10 or more inches, depending on the material to be sintered. The 6 ft. by 8 ft. pan represents the smallest commercial unit and has a capacity, under ordinary conditions, of about one ton of sinter per charge. The 10 ft. by 24 ft. pan is the unit for the larger installations, and has a capacity of from 150 to 250 tons per day of 24 hours. These larger pans are arranged to dump directly into standard railroad cars. A sintering plant usually contains from one to ten or more pans. The pans are made of cast-steel and are practically indestructible. They are rotated on hollow trunnions by means of a special mechanism. When the sintering is completed the pans are rotated to dump the sinter and rotated back into position for a new charge. The small pans may be dumped without any special rotating mechanism. Connection is made with the exhauster by means of a stuffing-box at the ends of the hollow trunnions.

The exhauster is usually of the regular fan type. It is rotated at a high speed and has to be well made and the exhaust-wheel well balanced. A suction of from 30 to 35 in. of water is easily obtainable in the pans by this means. This is due largely to the fact that in the stationary charge there is no leakage and all the air and gases have to pass through the charge to get at the chamber below and through the hollow trunnions to the exhauster. There is an advantage in using a high suction. The sintering is more uniform, there is less unsintered fine, and the sinter is firmer and in larger chunks. In sintering iron-ore flue-dust, if the coke content is a little high, water is sometimes showered on the charge to cool it during the sintering. The temperature on such occasions may rise so high as to liquefy portions of the charge. The best way, however, to avoid this condition, is to work with a lower combustible content. It is, of course, desirable to sinter a charge at as high a temperature as practicable to get a firm sinter and as large chunks as possible, for the reason that the firm hard chunks add considerably to the desirability of the sinter in the operation of the blast-furnace.

The charge-car receives the mixed material and delivers it to the pan. In charging the pan, the car spreads a porous bed, or layer, of non-sinterable material over the grates, delivers the charge on top of the permeable layer, and levels the charge even with the top rim of the pan. This is all done in a few seconds, while the car travels with moderate speed over the pan. The charge-car is usually motor-driven, but may be

moved in any other convenient way. In small units the pans may be charged with hand-labour by simply spreading a permeable layer over the grates and shovelling in the charge and levelling it. This adds somewhat to the cost of sintering, but saves a little in the cost of installation. It may also do as a temporary expedient. The porous bed, or permeable layer of non-sinterable material, which usually varies from ½ to ¾ in. thick, serves several important purposes: it prevents the fine material of the charge from passing through the grate; it serves to distribute uniformly the air passing through the charge; and it prevents the charge from being sintered to the grates. If the charge were placed directly on the grates and the sintering completed, the charge would be sintered to the grates and the removal of the sinter would be difficult and expensive; besides the grates would be quickly destroyed. This porous bed acts as a buffer between the grates and the charge, so that when the pans are inverted the entire charge drops out and leaves the grate clean. The porous bed may be any comparatively non-sinterable material, such as fine sinter, crushed limestone, or crushed silicious or oxidized ore.

The ignition is one of the most important steps in sintering. Unless the ignition is uniform, the sintering will be uneven and some of the charge will remain unsintered. If the ignition is uniform the sinter will always be good on a suitable charge, and little fine will have to be returned. Manifestly, the quick and uniform ignition of the entire surface of the charge presented something of a problem, especially in connection with the 10 ft. by 24 ft. pans. This problem was thoroughly solved by the ignition-hood, or igniter, which temporarily covers the charge while the ignition-fuel is projected over the entire surface of the charge. The air for the combustion is sucked through the numerous perforations in the hood. The ignition-fuel may be oil or gas. Both are being used successfully. Crude oil is satisfactory. Distillate, or kerosene, is a good ignition-fuel if cheaply obtainable. Gas is usually cheaper than oil. Either natural gas, blast-furnace gas, or producer-gas may be used and are giving excellent results. The combustion should be complete. A sooty flame is not as good as a flame which does not show any unconsumed carbon. The oil or gas is so finely atomized and so intimately mixed with the inrushing air through the perforations in the hood that there is little or no difficulty in getting a clear flame. When the combustion is complete the temperature in the igniter is intense. The ignition can usually be made in a minute. The igniter itself does not become very hot; this is due to the cool inrushing air and to the momentary time required for ignition. In the operation of a commercial plant the igniter is mounted on wheels and runs on the same tracks as the charge-car. The hood, or igniter, is normally about half an inch above the upper rim of the pan, so that it can be freely moved over all the pans. When ignition is to be made the hood is temporarily lowered, and makes a close connection with the pan, so as to give a uniform ignition over the entire surface of the charge, and especially around the edges. If it were not for this, the inrushing air around the perimeter of the pan would divert the flame, and result in incomplete ignition. When the ignition is made, the hood is raised, and the igniter is ready for another pan. After the ignition has been made, the sintering of the charge proceeds without the igniter. The igniter is usually motor-driven, the same as the charge-car. For the smaller pans the igniter may simply be pushed from one pan to the other. If oil is used for ignition, it will usually take from 0·75 to 1·0 gallon per ton of sinter. In a small plant, in Mexico, sintering copper concentrate and flue-dust, the oil consumption was materially reduced by sprinkling a little waste coke or charcoal dust over the top of the charge. It was found, in this connection, that, if fine coke or charcoal were mixed with the sinter charge of copper concentrate and flue-dust, much of the carbon would remain unconsumed and fixed in the sinter so as to make it available in the blast-furnace.

The sintering of a charge may be briefly described as follows: The mixed material, as also the porous bed, is delivered to the charge-car; the car is then run over the pan, and in passing over it the porous bedding is uniformly spread over the grates by the distributor at the front of the car, and the charge immediately placed upon the bedding and levelled off with the top rim of the pan. This usually takes less than a minute, even for the 10 ft. by 24 ft. pans. The exhauster is then started, or switched on to the pan. This creates a strong downward draft of air through the charge. The igniter is then run over the pan and the ignition-fuel, under a high pressure, is atomized over the charge and ignited. The flame and hot products of combustion are sucked down through the charge and completely ignite the surface, usually in less than a minute. The igniter may then be removed and used for another charge. The time of sintering may vary from 15 to 60 minutes, depending on the nature of the material and the results desired. The suction may vary from 10 to 35 in. of water. It is usually higher at the beginning than at the end of the operation, for the reason that at the beginning the mass is not as permeable. With a high suction, there is not so much danger of short circuits of the air through the charge; when a short circuit occurs, the temperature at that point becomes so intense as to cause fusion, which automatically has a tendency to close the larger air-passages through the partly sintered charge, and make the sintering more intense at other portions. When the sintering is complete, the exhaust is shut off, the pan mechanically rotated, and the sinter dumped. The pan is then rotated back to its normal position, and the cycle repeated. In some of the large plants the cycle is completed in about 20 minutes

The power required for sintering depends somewhat on the nature of the material to be sintered. Ordinarily, it will be from 5 to 6·5 kw.-hr. per ton of sinter. The repairs are small and consist principally of the replacement of grates.

Several interesting problems arise in reference to sintering by the present method. One is the possibility of sintering concentrate for shipping instead of drying. Sintering requires about 10% moisture. Drying of the concentrate, if sintering is contemplated, would therefore be unnecessary and could be eliminated. Concentrates contain their own fuel for sintering, as opposed to extraneous fuel which has to be purchased for drying. The sinter would be ready for smelting, and the shipping weight would be reduced to from 15% to 20% from the ordinary dry-shipping weight. This reduction in weight is due to the replacement of the sulphur with the lighter oxygen, to the elimination of the water of hydration, to the elimination of other volatile elements, and to the evaporation of the uncombined moisture, which in ordinary drying is never complete. A reduction of from 15% to 20% in the shipping and smelting weight will ordinarily much more than pay for the sintering. If the sulphur content in the concentrate is too high for sintering, the charge can often be diluted with fine shipping ore low in sulphur, and this would tend to give a greater porosity to the sinter charge, especially in the sintering process as applied to the treatment of flotation concentrate.

ELECTROSTATIC DEPOSITION OF POTASH-BEARING DUST.

At a meeting of the Cleveland Institution of Engineers held at Middlesbrough on February 7, E. Bury, A. Bury, O. Ollander, and F. Bainbridge presented a paper on the electrostatic precipitation of dust from blast-furnace gases and the extraction of potash therefrom. In our issues of February and March, 1918, we quoted a paper and a discussion on it relating to this subject read before the same society. The present paper gives further information in the light of subsequent experience. The paper contains two themes, one the electrostatic precipitation of dust, and the other the extraction of potash in the form of soluble salts. We quote the first part of the paper fully, because it reviews the subject generally. Hitherto most of the literature on the subject has come from the United States, and consequently many people think that the idea originated with Dr. Cottrell. The present paper puts the matter in a more correct light historically. The second part of the paper contains much information of use to those who are engaged in separating mixed salts.

Precipitation of Dust.—The formation of dust and fume in the iron blast-furnace takes place in four ways: (1) Dust carried in with the burden, namely, coke, ironstone, and limestone dust; (2) dust caused by attrition between the pieces of material as they descend the furnace; (3) dust caused by spalling-off of particles as the materials become heated; (4) fume, the result of volatilization of various chemical substances, particularly of chlorides, in the case of Yorkshire ores. The first three, while usually constituting by far the greater portion of the dust, are also the most easily removed, as their carriage is almost entirely dependent on the velocity of the gas stream. It has been stated by one writer on the subject that the quantity carried varies as the square of the velocity of the gas, and this seems reasonable for particles of a mechanical size. By "mechanical size" is meant particles large enough to obey mechanical laws, in contrast to particles so small that they may be compared to colloids, and will behave in a manner similar to a vapour or fume, in which case the law of the square of the velocity will not apply. Another writer quotes a statement that the dust carried varies as the seventh power of the velocity, but it seems difficult to believe such can be the case

There remains the fume, the smallest proportion of the total dust in the gas, the most difficult to remove, and usually the most valuable when recovered. It is formed low down in the furnace, and is due entirely to the heat volatilizing or subliming the various constituents, whose quantity depends entirely on that of the constituents contained in the burden. With regard to the water vapour, this will condense on a fall of temperature to below the dew-point, and consequent lowering of the gas velocity, and probably bring down a little of the chemical fume with it. The fume may be compared to the colloidal state of matter; that is, matter so finely divided that when mixed with a liquid it is beyond the laws of gravity, and refuses to settle out even after prolonged rest, unless some other influence is brought into action.

The authors have had the opportunity of inspecting two plants working under the Halberg-Beth system, and a very high efficiency has been reported. In one case the gas has been cleaned down to 0 007 gramme per cubic metre. The method employed is, after cooling below dew-point, to condense the water vapour, and then, raising the temperature to slightly above the dew-point to avoid any further deposition of moisture, to pass the gas through the filter-bags, where the dust is trapped. Apart from the loss of the sensible heat of the gas, the plant is elaborate mechanically, and occupies a larger ground space than the other methods.

With regard to the Kling-Weidlin system, the authors have had no experience of this, but have heard excellent reports. It consists of a mattress of steel fibres, through which the gas is passed, and is periodically shaken to remove the dust caught in it. It should be easy and inexpensive to install, it requires small space and little attention, and has the advantage of removing no sensible heat from the gas. The authors have seen a sample of the dust removed by this method, where it was installed on a plant using hematite ores. This dust was very different from that to which the authors are accustomed at Skinningrove, Yorkshire, being of a hard, gritty nature, with particles of a relatively large size. They are prepared to believe that, where dust of this character has to be dealt with, the Kling-Weidlin mattress will be highly efficient. They are afraid, however, that where fume exists in the dust to more than a minute extent the mattress will be clogged very rapidly, and no amount of shaking will dislodge it. Deposited fume such as exists at Skinningrove is a most difficult material to dislodge, even when hanging on a perpendicular surface, and the problem has not yet been solved to the authors' entire satisfaction.

Coming now to the electrostatic method of deposition, Sir Oliver Lodge about 1880 patented a method of depositing smoke for making lamp-black, and in later years considerable attention was drawn to his suggestion for the dispersal of fogs—which consist of water vapour and smoke intimately mixed—by means of an electric discharge, such as is given by a Leyden jar or Wimshurst machine. In recent years this method was employed on a practical scale by both Lodge in England and Cottrell in America for condensing SO_3 fumes in sulphuric acid concentrating plants. The latter also applied it to the recovery of dust from blast-furnaces employed in reducing copper ores. Both employ identically the same principle, the main differences between the two systems being in the manner in which the electrostatic discharge is generated and then applied to the gas stream. In the case of the Lodge system the discharge is generated by means of a static transformer of the induction-coil type, selective devices being employed for rectifying the discharge, so that it is uni-directional. Only a portion of the discharge is employed, namely, the "peak of the break," that is, the most intense portion. The apparatus employed is very light in character, and for the quantity of gas treated at Skinningrove a large number of such units are required, 32, or two to each chamber. So that it may be said that one of the features of this system is that practically standard units are employed, the number varying with the type and quantity of gas to be treated. The Cottrell system, on the other hand, employs much more massive plant for generating the discharge, consisting of a rotary transformer and rectifier, designed in accordance with the whole requirements of the plant, and only divided into units for purposes of stand-by, etc.

As regards the discharge electrodes in the gas stream, the Lodge system at Skinningrove employs an arrangement of vertical steel plates about 18 in. wide and 10 ft. long, placed edgewise to the flow of the gas in staggered rows, and standing on a grid of light sections, which are earthed. They are built to form a unit of 85 plates. Suspended between them from insulators in the roof of the treater chamber are vertical steel tubes, provided with discharge points on either side of

one diameter, and pointing to the steel receiving electrodes immediately opposite, on which the dust is deposited. Such a unit of electrodes is served by one of the discharge generating units already described, and two of them are installed in each chamber. The dust is removed by cutting off the gas flow, and striking the grids supporting the plates from below with hammers, and in the case of the discharge tubes by striking the frame from which they are suspended.

In the Cottrell system, vertical cast-iron pipes about 11 in. in diameter are employed, arranged in batteries and set into a header at their tops, which communicates with the dirty gas main, their lower ends standing on grids carried over the hopper in which the dust is deposited, with a side exit opening into the clean gas main. Hanging down the centre of each pipe is the discharge electrode, a chain sometimes being employed. The discharge passes from this electrode to the wall of the pipe, the dust being removed by mechanically-operated hammers striking the outside of the pipe, and by a shaking arrangement for the discharge electrodes. It is obvious that such an arrangement must occupy a much larger space for a given quantity of gas if the velocity is to be the same as the Lodge system. The authors have been informed, however, that the Cottrell operates at a velocity of 5 to 6 ft. per second, as against the Lodge at Skinningrove at 3 ft. per second. The Cottrell, however, employs considerably more power than the latter.

These are the main differences between the two systems. In both systems it is essential to high efficiency not only that the discharging electrodes should be all symmetrically disposed with regard to the receiving electrodes (plates or pipes), but that the gas should pass through them in an even, steady stream, with neither concentrations nor idle pockets. Should such conditions occur, dust will pile up unevenly on the discharge electrodes, so providing shorter paths for the discharge in which it will naturally concentrate, the result being that other electrodes will be robbed of discharge, no dust will be deposited thereon, and a free passage will be given to dirty gas.

The plant at Skinningrove consists of 16 chambers in parallel through which the gas is passed, each chamber containing two of the units of electrodes aforesaid, in tandem. Any chamber can be isolated for inspection, repair, etc. The plant is constructed of ferro concrete, and although some cracking of the chambers and gas mains has occurred, it has not happened to any serious extent, and in future structures could be largely avoided by a better disposition of the steel reinforcement, to take the bulging stresses set up under the influence of heat. The 32 discharge generators are stationed in the top floor, which rests on sliding shoes to allow for expansion, on the chambers proper. The space between the top floors and the roof of the chambers is occupied by the leads from the generators to the insulators from which the discharge electrodes are suspended, the arrangement ensuring a very short and sheltered path for the discharge from the generators to the chamber, thereby reducing leakage to a minimum. The chambers themselves, also resting on sliding shoes, are carried by the bridge over the slag tunnel.

Extraction of Potash.—The soluble constituents of the flue dust obtained from the electrostatic plant at Skinningrove Ironworks are almost entirely in the form of chlorides, only very minute traces of sulphate being present and carbonate and cyanide not at all. The average analysis is as follows: Soluble potassium chloride, 20%; soluble sodium chloride, 8%; soluble calcium chloride, 7%. On this account the separation of pure potassium chloride presented few difficulties. The method of separation finally decided upon is divided into two stages: (1) Separation of the sodium and potassium chloride from the calcium chloride as a mixed salt. (2) Separation of the potassium chloride from the sodium chloride. The first stage is accomplished by direct evaporation, and is rendered possible by reason of the extreme solubility of calcium chloride as compared with the solubility of sodium and potassium chloride, 31·7 kg. of calcium chloride requiring rather less than 49·1 kg. of water for solution. If, therefore, the strong liquor be evaporated to this concentration and cooled, 90% of the potassium chloride and sodium chloride will be thrown out of solution. It is possible further to reduce the KCl and NaCl content of the liquor, but as the calcium chloride may be used to remove the carbonate from alkali-carbonate-bearing flue dusts by double decomposition, there is no need to endanger the purity of the mixed crystals by further concentration.

The second separation is based on the fact that the solubility of potassium chloride increases with the temperature, while the solubility of the sodium chloride decreases, according to the following table of solubility in grammes per 100 grammes of water:

Deg. C.	KCl.	NaCl.
0	11·2	30·0
25	15·8	29·0
50	22·0	27·7
70	27·3	26·8
80	30·0	26·4
100	34·7	25·8

On evaporating the solution no crystals are deposited until a density of 46° Tw. is obtained, when the solution is saturated with potassium chloride. If evaporation be now continued, potassium chloride crystallizes out until a density of 49·5° Tw. is obtained. At this point, the solution is cooled and potassium chloride crystallizes out, finally reaching 25° C., which is the lowest temperature in actual practice. The solution is reheated to a point at which the solution is saturated with sodium chloride but not with potassium chloride. Evaporating further, sodium chloride will be deposited, and if the solution be filtered hot to remove the sodium chloride, potassium chloride again crystallizes out on cooling. The operations now become a cycle.

The dry dust from the conveyor is lixiviated with water or wash liquor as it falls from the conveyor chute into the concrete slurry tanks below the electrostatic plant. In order to prevent any settling this slurry is circulated continuously through the chute and agitated with blast, thus producing an intimate mixture, only enough water or liquor being added to produce a slurry thin enough to be pumped through the circulating system and to the mixers. In the mixers, which are steel vessels of about 800 gallons capacity, and provided with efficient stirring arrangements, the slurry is boiled and then continuously run down on to a series of revolving vacuum-filter drums situated below the mixer. The filter drums, which are 3 ft. 6 in. diameter, and 7 ft. 6 in. long, are built of oak laths 3 in. apart covered with a strong wire net, which carries the filter cloth. To protect the cloth an ⅛ in. steel wire is spirally wound round the drums, which are driven by a worm-gear and revolve at 3 to 4 revolutions per minute. The wells in which the drums revolve are built in concrete with a cast-iron front, and in order to prevent any settling they are made V-shaped, with a stirrer revolving along the bottom. The dried cake containing about 50% moisture is cut off by a steel knife placed in such a position that the cake flaked off from one drum falls into a repulping trough, and from there into the well of the next drum. In order to break the cake up into a thin slurry

this trough is fitted with a stirrer and an air lift, which continuously circulates the slurry from the drum well through the trough. All feed liquors for each drum are also fed into these troughs so as to get an intimate mixture. By having four drums, four consecutive washings with liquor of falling strength are obtained, the last washing being done with water; and the last cake, free from soluble salts, is transferred by a worm conveyor to railway trucks outside the building, whence it is returned to the blast-furnaces. The liquors from the four drums are drawn off by vacuum into separate tanks, and from there delivered intermittently to the respective storage tanks. The strongest liquor of about 30° Tw. from No. 1 drum is treated with air and lime if any soluble iron salts are present, and then filtered through a sand filter and delivered to the preliminary evaporator. The liquor from No. 2 drum goes to the slurry tanks, the liquor from No. 3 drum is used for washing in No. 2, that from No. 4 drum for washing in No. 3, and No. 4 receives water. The strong liquor of about 30° Tw. is transferred to a feed tank for the preliminary evaporator, and continuously fed into a Kestner salting-type evaporator, in which the separation of the sodium and potassium chloride from the calcium chloride takes place. The crystallization starts at about 62° Tw., and continues to about 94° Tw., when the liquor is approximately saturated with all three salts; above 76° Tw. the evaporation is very slow, and very little mixed salt is obtained. The liquor also becomes very viscous above this density and is difficult to filter. The evaporator is therefore emptied at this point and the solution allowed to cool, whereby a crop of crystals is obtained which contain approximately 10 to 15% calcium chloride, the remainder being a mixture of potassium chloride and sodium chloride. The mother-liquor drained from the above contains 90% of the total calcium chloride and only about 5% of the total potassium chloride in the original dust, and is further evaporated to dryness in open pans. After the mother-liquor is drained off, the crystals are dissolved in water or feed liquor for No. 1 evaporator, and returned to the feed tank for this evaporator. The crop of crystals received during the evaporation from 62° to 76° Tw. is from time to time emptied out of the separator of the evaporator on to a vacuum filter, the mother-liquor drawn off, and the remaining mixed salt washed twice with a hot saturated mixed salt solution in order to remove the calcium chloride, which generally amounts to 1 to 3% in the unwashed salt, the wash liquor being each time returned to the evaporator. The mixed crystals are dissolved in hot water in a tank. The resulting liquor of about 30° is filtered through a brick filter and passed on to the feed tank, from whence it is fed into the evaporator Evaporation is then commenced and continued until the liquor has a density of 49° Tw. During this evaporation potassium chloride crystallizes out, and more liquor is added until the evaporator is completely full of liquor of the required density, at which point the whole contents of the evaporator are run out and passed through a revolving crystallizer, more potassium chloride being deposited during the cooling. The mother-liquor is drained from the crystals in a centrifugal hydro-extractor and returned to the feed tank, from which it can either be supplied to the crystal dissolver, or to the evaporator for further evaporation. In the latter case the liquor is evaporated until the density again reaches 49° Tw., but owing to the saturation of the liquor only sodium chloride is thrown out of the solution during this second evaporation. The sodium chloride is removed from the evaporator by means of the vacuum filter box, and the clear liquor run through the crystallizer, when potassium chloride again crystallizes out. From this point the process is cyclic, sodium chloride crystallizing out on evaporation and potassium chloride on cooling. It is obvious, of course, that the above operations may be varied, and modifications are made from time to time in order that the final evaporator may be kept full of concentrated liquor. All crops of potassium chloride are washed twice with a cold saturated solution of potassium chloride in order to remove the last traces of mother-liquor, so as to produce a product containing at least 98% of potassium chloride.

Quicksilver Mining in China.—At a meeting of the Cornish Institute of Engineers held on February 19, Frank Trythall read a paper describing the mining of quicksilver in the Toon-Yen prefecture, Kwei-chow Province, South China. Quicksilver has been extensively mined in Kwei-chow, for how long no information can be obtained beyond the assertions of the landowners, who claim that their ancestors were mining for quicksilver during the Ming Dynasty (1368-1644). Gunpowder was introduced for the first time as an explosive about the year 1870 by miners from Sze-chuan. Previously fire-setting and the hammer and gad were the only means of mining. The geological formation of the region is magnesian limestone, in horizontally stratified beds of several hundred feet in thickness. The mineralized zone is roughly three miles square. The quicksilver deposits are not continuous, and they are irregular in shape. The country is cut by canyons running in various directions, and it is noticeable that those deposits which are near the rim of the canyons are richer and more extensively worked than those occurring farther afield. The ore occurs: (1) As impregnation of well-defined beds of limestone; (2) along the joints, cracks, and planes of stratification; (3) in isolated bunches, nests, or pockets, and in vughs or cavities which contain crystalline aggregates or well developed crystals of cinnabar in the form of penetration twins of two rhombohedra, associated with quartz and calcite; (4) irregularly disseminated through a number of beds which have, in most cases, undergone considerable local disturbances. There are two varieties of cinnabar. One is a bright, transparent red, the other a dark, opaque red with which antimony is almost invariably associated in small quantities. The former is known as the "red," and the latter as "black" cinnabar. Pyrites is entirely absent. Native mercury is occasionally met with, associated with the antimonial ores. These deposits are similar to, and characteristic of, others in the districts of Beh-mah-tung, Wuchuan, and Pachai.

The methods employed in mining and smelting are distinctly crude, and conform to no laws or regulations. About the time of the writer's visit, mining regulations were issued by the Imperial Government, but were never enforced, nor was the slightest notice taken of them. In the mines known as "private" mines, which have been acquired by a company, the miners are required to sharpen their own drills before entering the mine, and drill and fire two 15 in. holes. They drill single-handed with 7 lb. hammers, a back hole counting double. The drills, ⅞ in. diameter, are of iron, pointed with steel at both ends. Other mines, described as "public," are usually old workings which have been abandoned by companies as too poor to work, but still containing patches of sufficiently remunerative ore for individual miners, who are allowed to work them on payment of 600 cash (1s. 7d.) per month, known as "hammer tax," to the local magistrate. The miners work either on day's pay or on tribute. In the first case the hours worked amount at most to six; but every fifth

day, being market and pay day, is regarded as a holiday, when they receive 400 cash (about 1s.). In addition to the wages they are supplied daily with two meals, consisting of boiled rice and vegetables, and on market days a small portion of pork. The meals cost roughly 50 cash or 1·6 pence each. Thus a miner on day's pay earns, inclusive of his food, 130 cash (4·2 pence) per day, and works at the outside 24 hours in 5 days. Overtime is paid on all holes drilled above two in a shift at the rate of 1·2 pence per hole. The tributer supplies his own tools, explosives, etc., and works without restriction on a piece of ground allotted to him by a company, and his ore has to be taken to the company's smelter for treatment. He is paid for the quicksilver so produced at a rather lower rate than the prevailing market price, and, in addition, the buyer retains such mercury as remains in the furnace. All taxes are paid by the company to the officials and land-owners, whether the mines are worked on day's pay or tribute. In the blasting operations, after the hole has been drilled to the required depth, a pricker is inserted and from two to three ounces of gunpowder are tamped around it with an iron rod, after which the hole is filled with clay, or fines, nearly to the top. The pricker is then carefully withdrawn by twisting it with a pointed bar inserted in the eye of the pricker, and, in the space thus left, the fuse is introduced and a conical-shaped piece of paper attached to the end of the fuse, which, on being lit, smoulders and acts as a time fuse until it reaches the powder. The native fuse consists of a peculiar kind of brown paper, treated with nitre, and rolled very tightly, enclosing a minute quantity of gunpowder. When finished it has the appearance of a piece of whip cord. The timing is very unreliable. Owing to the inferior quality of the gunpowder (which is made on the mines from ingredients obtained locally), the explosive force is small, only from 200 to 300 lb. of rock being dislodged per hole drilled.

No system of driving, sinking, or stoping is observed in the winning of the ore, the miner simply following a stringer on a mineralized band of ore, enlarging or reducing his working face as the mineral widens or pinches, resulting in a series of intricate workings. Timbering is unnecessary, as the ground is compact and holds well, even in the largest workings. The ore is transported from the working face to the surface by means of baskets carrying 30 to 40 lb., fastened to the coolie's back by ropes which pass under the arms. In the very low and narrow workings where it is impossible to stand upright, wooden boxes containing the ore are drawn along the floor by small boys, crawling, with a rope passing around the neck, down the stomach, between the legs and attached to the box. On the ore reaching the surface, coolies, termed ore pickers, cob and pick it, as much as possible of the barren rock being discarded. The large crystals of cinnabar are detached by means of a stout pointed wire. The ore is crushed on a large flat stone with hammers, to pass a ⅛ in. bamboo sieve, and if the cinnabar is of the red variety, it is panned, the concentrates removed, and the tailings treated for quicksilver in the furnace retort. If the cinnabar is black, the panning is dispensed with, and the whole put direct into the furnace.

During the winter months, when agricultural labour is more or less at a standstill, a large percentage of the population turn their attention to the working over of the old dumps, and may be seen wending their way to the dumps at all hours of the morning, armed with a basket, hammer, and rake, and sometimes a lamp to enter the abandoned mines, returning in the evening with perhaps 10 to 15 lb. of picked ore containing 1% to 2% quicksilver. This ore is disposed of to the owners of private furnaces, of which there are a number scattered about the district. Pumping is a minor item, from the fact that the deposits are not deep-seated, and the deeply carved and fissured country does not permit of the accumulation of large quantities of water, which would prevent the natives from carrying out their primitive modes of mining. Where water accumulates in sufficient quantities to check operations, a bamboo or wooden chain-pump is installed, similar to those used for irrigation purposes, but if they prove inadequate, the workings affected are abandoned until the water recedes. Ventilation is also a question which does not worry the Chinese miner. The imperfect combustion of the explosive, the smoke arising from the oil lamps, the filthy habits of the miners themselves, and the fact that many absolutely live in the mine for fear of having their rich ore stolen, tend to make the air as foul as it is possible to conceive, and often, on entering a working, it is almost impossible to see how many are at work or what is being done. The miners will submit to all these discomforts and dangers to health rather than do any work which would cause expenditure without direct remuneration.

The furnaces, built in pairs, are 2 ft. 6 in. in diameter and 1 ft. 6 in. in height. Each consists of a cooking pan, which serves as a receptacle for the ore, resting on a round fire-place made of unburnt bricks, on which is placed a similar pan inverted, with a 12 in. hole in its centre. On this is built a collar of clay, 12 in. high, strengthened by a plaited bamboo network, extending a few inches above the clay collar, serving as a support to the upper pan. The top of the clay collar is grooved in the centre, and a third pan, with a 12 in. diameter hole, rests on its inner rim, and this, being covered by an earthenware pot which acts as a condenser, an annular space is formed between the groove, the lower part of the top pan, and the inner side of the bamboo network. Three holes ¾ in. diameter are pierced through the rim of clay on which the topmost pan rests, and are known as "percentage holes," inclining towards the centre of the furnace. The amount of quicksilver collected in this annular space depends on the inclination of the percentage holes, increasing in quantity as the angle of inclination increases. The earthenware pot or condenser is luted with fine residues and the bamboo network is lined with clay. Wood fuel is used for heating purposes. The usual charge for one furnace is 50 lb. of ore. The quicksilver vapours condense in the annular space and earthenware pot, which is changed at intervals until the ore is exhausted, when the residues are withdrawn by means of a shovel the blade of which is at right angles to its handle, and replaced by another charge. While the condenser is being changed, the ore in the pan is stirred with a wooden pole, the fumes escaping copiously during the operation. The condenser becomes coated with minutes globules of quicksilver, which on removal are run together by rubbing the surface with a rag forming a pool at the bottom of the pot. The losses, as far as can be estimated, vary between 30% and 40% of the total quicksilver. The amount collected in the condenser naturally depends on the richness of the ore treated, and sometimes as much as a catty (1·3 lb.) is collected. The metal is poured into bamboo flasks and eventually transported to the river ports in pigs' bladders. The residues, especially in the case of rich ores, which still contain imperfectly burnt ore, are ground by hand, sluiced, and the concentrates again retorted.

In addition to the furnaces at work near the mines, considerable numbers are owned by individuals who carry on custom smelting, receiving in payment the quicksilver collected in the annular space through the

percentage holes. The ore treated in these furnaces is obtained from the mines or from the dumps, and not infrequently by theft. The owners of private mines have a set of furnaces for rich ore, and another for poor ore, and, if the miner strikes a rich pocket, the ore is treated in the rich-ore furnaces, the percentage holes being so inclined that the furnace owner receives about 40% of the total distillate as his share. This is an established custom to which the miners willingly conform.

Bauxite in West Africa.—The report of Mr. A. E. Kitson, the Director of the Geological Survey of the Gold Coast, for the year 1919, just to hand, contains further information relating to the bauxite deposit at Mount Ejuanema discovered by him previously, and described in his report for 1917. The latter report was quoted in our issue for July, 1919, and we reproduce the more recent report herewith. It will be seen that some interesting notes are given, of value to those interested in the formation of bauxite.

The whole of the shafts at Mt. Ejuanema sunk through the bauxite deposits were carefully examined, the character of the bauxite noted, and numerous samples from top to bottom taken for analysis or record from nearly all the shafts. These shafts number 65 on the flat top of the mountain and 68 along the sides. The shafts on the top vary in depth from 19 ft. to 31 ft. to the bottom of the bauxite, or 23½ ft. to 33½ ft. in total depth. Those on the sides vary from 3½ ft. to 15½ ft. of rubbly and massive bauxite with soil, and in total depth from 4½ ft. to 33 ft. As disclosed by the shafts the average thickness of massive and rubbly bauxite, with interstitial finely granular bauxite, like red soil, is 20¼ ft. The massive bauxite is 12½ ft. thick, and the rubbly bauxite 7⅝ ft., but it is impossible at present to form more than a very approximate estimate of the proportion of red soil to the rest. Analyses of this material are in hand; those already received prove almost the whole of it to be bauxite. The surface soil, which is also probably very finely granular bauxite, has an average thickness of 2 ft. 10 in. It occurs only on certain parts of the top of the mountain, for massive bauxite outcrops cover considerable portions of it. The average of 17 analyses already made of bauxite from various portions of the deposit gives the following percentages: Al_2O_3, 60·55; Fe_2O_3, 9·75; TiO_2, 2·21; $CaO+MgO$, 0·73; SiO_2, 1·42; water, 25·59. The total quantity of bauxite on the mountain may be taken for the present at approximately 3,000,000 tons.

An interesting feature connected with the bauxite is that in many of the deeper shafts on the top of the mountain there was so much bad air caused by carbon dioxide that complete observations could not be made in all of them. In many cases the light of a lantern lowered into the shafts went out instantaneously on reaching depths varying from 5 to 15 ft. from the bottom of the shafts. Time did not permit repeated visits to these shafts, nor to exhaust the bad air by extemporized means, while no tornadoes supplied water when wanted to dissolve the gas. Consequently some 10 shafts have not been completely examined, for it was found that, even protected by a rope for rapid haulage, it was not safe to venture down owing to the bad effects of this gas. The source of the carbon dioxide is undetermined, but there is presumptive evidence that it is being exuded from the pores and cracks in the bauxite. It is certainly not due to decomposing vegetation fallen into the shafts, or to exhalations and exudations from the native workmen. Only some of the shafts, and those not the deepest, showed the presence of bad air. In one case a shaft being sunk was found the following morning to be so foul that the light vanished at once 10 ft. from the bottom. Many shafts, 20 to 30 ft. deep, with 6 to 18 in. of decaying vegetable matter, had no foul air, for no bad effects were felt at the bottom. Further, rats, mice, a squirrel, frogs, snakes, lizards, and insects of various kinds, which were found at the bottoms of many shafts, were quite lively, and even when burrowing into the material at the bottom seemed to suffer no ill effects. In other cases, usually in shafts without vegetable matter, they were somewhat torpid, possibly from starvation or injury. If carbon dioxide is now coming from the bauxite, there seems to be no reason to doubt that, dissolved in water, it is acting on the clay-shales and assisting in the formation of bauxite. Should this action be taking place, it is evident that bauxite is still in process of formation.

Flotation Applied to Coal.—Reference has been made in these columns on several occasions to the application of the Minerals Separation process to the flotation of coal and the means thereby secured for separating fine coal from the dusty or slimy material obtained from the screens or coal-washers respectively.

A paper on this subject was read by A. F. Bury and A. Bicknell before the Newcastle section of the Society of Chemical Industry on January 26. The authors said that the methods for separating impurities from coal had hitherto depended on the fact that coal was of less specific gravity than the waste, and the use of jig washers, tables, and other forms of gravity separators had been steadily perfected. All the machines developed for that purpose, however, had failed to treat in an efficient commercial manner the finer portions of the coal. Such a method had been evolved by the Minerals Separation, Ltd., whose froth-flotation processes had already created a revolution in the dressing of metallic ores. The experiments carried out by Minerals Separation, Ltd., showed that their flotation processes could be modified and adapted to the recovery of the large amount of coal daily going to waste in washery pit refuse, and to the reclaiming of the vast tonnage of coal thrown away in previous years. In 1919 it was suggested to the Skinningrove Iron Co. that the process thus developed might be employed advantageously for the purification of coal for the making of coke for blast-furnace use. Investigations showed beyond doubt that the process offered a means for the production of coal of very low ash, and subsequent coking tests showed how admirably the washed coal was suited to the production of the finest metallurgical coke.

Coal as delivered at the works might be briefly said to consist of a mixture of the following substances in varying proportions: (1) pure coal, having a low ash of from 2·5 to 5·0%; (2) bone coal, having a higher ash of from 10 to 16%; (3) shale containing a varying amount of bituminous matter and an ash of from 60 to 85%; (4) small quantities of other impurities such as gypsum and pyrites. The shale, gypsum, and pyrites could be removed by mechanical means providing the coal was crushed sufficiently fine to ensure that the shale was freed from coal, the degree of fineness varying with the extent to which the coal and shale were interstratified. The bone coal presented quite a different problem. Most Durham coking coals appeared to contain approximately 10% of the high-ash coal, in which the ash was so intimately mixed or even chemically combined that no separation was possible by mechanical means. It had been found that the ash of the bone coal could not be removed or reduced even when the coal was ground to pass a 200 mesh screen. The separation of the bone coal from the better qualities was one of the most striking features of the flotation process, and, it was believed, unattainable by any other method of coal purification.

Silver-Lead in Yukon. The *Canadian Mining Journal* for January 21 contains an article by W. E. Cockfield on silver-lead ore deposits in the Mayo district, Yukon Territory, some distance east of Klondyke. The press has contained news from time to time during the last few years of these discoveries, and brief references to them have been made in the publications of the Canadian Geological Survey. As attention has recently been attracted to them again, it is opportune to quote Mr. Cockfield's article.

In the year 1914, with the opening of the rich deposit at Galena creek, an impetus was given to the search for argentiferous galena, which resulted in the discovery of a number of promising properties. These include Keno Hill, Lookout Mountain, Rambler Hill, Stand-to Mountain, Mt. Cameron, and a number of others.

Keno ridge is a long wedge-shaped ridge lying between the heads of Lightning Creek, Christal Creek, and Ladue River about 42 miles from Mayo by road. It has the characteristic flat top of the Yukon plateau country, and is surmounted by a number of hillocks known locally as Keno Hill, Minto Hill, Monument Hill, Caribou Hill and Beauvette Hill. Upwards of 600 claims have been staked on the ridge, and on most of these sufficient work has been done to keep them in good standing. Real development work, however, has been performed only on a small number of groups. The geology of Keno Hill is similar to that of the greater part of Mayo area. The rocks exposed consist of a series of crystalline schists and gneisses, intruded by sills of greenstone and dykes and sills of rhyolite, quartz-porphyry, and granite-porphyry. The schist series is made up of gneissoid quartzite, quartz-mica schists, mica, and chlorite schists. The greenstone sills vary in colour, composition and texture, ranging from a diorite to a diabase. The acid sills and dykes are believed to be apophyses from a granite mass to the eastward. The strata in general have an east-west trend and dip to the south at low angles. Near the hillocks known as Keno Hill, Minto Hill, and Monument Hill, however, they undergo a sharp flexure, bending nearly at right angles, and in the vicinity of this flexure there is much local faulting. The ore-bodies are found in fissure veins and are consequently intimately related to the systems of faulting. Two such systems have been recognized, one of which is in a general way parallel to the trend of the strata and is referred to as longitudinal faulting; the other making an angle of 70° to 80° with these and cross-cutting the strata, is referred to as transverse faulting. In the longitudinal system one main fault traverses the ridge for several miles and in the vicinity of the flexure diverges into three main branches, which are also quite persistent. Traces of other faults parallel to these have been found, but owing to the rather heavy drift cover, they could not be followed any considerable distance. These faults are mineralized with quartz and arsenopyrite, and occasionally with galena, manganite, and siderite. The transverse faults occur in great numbers, particularly in the vicinity of the flexure. As a rule they are much shorter than the longitudinal faults and of relatively slight displacement. They are mineralized with galena, manganite, and siderite, and occasionally with calcite and blende. In both systems the galena is enriched in places with freibergite. The principal ore-shoots already discovered lie in the transverse faults. From what has already been learned it may be established as a general rule that where one of these fissures taps a longitudinal fault and passes upward out of a hard stratum such as quartzite or greenstone into schist, an ore-shoot will be found in the vein below the schist capping. In the longitudinal faults ore deposition has taken place at points where the older filling of quartz-arsenopyrite has been opened by a distinct fracture, but at some localities a disseminated ore occurs, which may have been introduced at the time of formation of these veins. The ore-shoots vary in width from a few inches up to 4 or 5 ft. The galena in them is fairly free from mixture with gangue minerals and samples are usually taken of the galena only. A content of about 200 ounces of silver per ton and 60% lead probably represents closely the value of the ore-shoots. None of these shoots has been fully blocked out as yet, and none of the deposits has been tested in depth. The galena occurs fresh and unaltered right at the surface, but on some properties carbonates are encountered at a depth of a few feet. In other cases no alteration was noted. It is expected that about 3,000 tons of ore will be hauled to Stewart river during the winter from these deposits. The Stewart discharges into the Yukon river 50 miles above Dawson City.

SHORT NOTICES.

Measuring Compressed Air.—At the meeting of the Midland Institute of Mining, Civil, and Mechanical Engineers held on January 22, J. L. Hodgson presented a paper on the metering of compressed air.

Mechanical Loading of Ships.—At the meeting of the Institution of Mechanical Engineers held on January 21, H. J. Smith read a paper on the mechanical loading of ships, giving much attention to the handling of minerals in bulk.

Working of Petroleum by Shafts and Galleries.—At the February meeting of the Institution of Petroleum Technologists, a paper was presented by Paul de Chambrier, describing the exploitation of oil deposits at Pechelbronn, Alsace, by means of shafts and galleries. This paper is an abstract of a pamphlet noticed in another column. By means of shafts and galleries the oil drains downward.

Flotation of Coal. — The *Iron and Coal Trades Review* for February 11 describes the application of the Minerals Separation flotation process to the recovery of fine coal from waste.

De-aeration of Solutions.—The December *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa contains a paper by H. A. White discussing methods of removing oxygen from solutions and water by the addition of chemicals and giving details of his experiments with tannin, ferrous ammonium sulphate, manganese sulphate, etc. The suitability of chemicals for this purpose depends upon price, insolubility after oxygen absorption, and freedom from undesired reactions.

Estimation of Mercury.—At the February meeting of the Newcastle section of the Society of Chemical Industry, A. A. Hall described a quick method for the estimation of mercury.

Knudsen Furnace.—In the *Engineering and Mining Journal* for February 12, E. H. Robie describes the use of the Knudsen furnace in the pyritic smelting of Sudbury nickel-copper ores, and the experiments undertaken by the International Nickel Company.

Zirconia.—At the February meeting of the Birmingham section of the Society of Chemical Industry, E. C. Rossiter and P. H. Sanders read a paper on the preparation of zirconia from Brazilian ores, giving also a new method of determination.

Fume Precipitation.—*Engineering* for January 28 describes the Cottrell electrostatic plant as applied to the precipitation of SO_3 fume at the sulphuric acid plant of the Holton Heath cordite factory.

Electric Smelting.—In *Chemical and Metallurgical Engineering* for January 19, Jonas Herlenius writes on the electric furnace used in Sweden for producing pig iron.

Helium.—The *Journal* of the Franklin Institute for February contains a paper by R. B. Moore, chief chemist of the United States Bureau of Mines, on the history, properties, and commercial development of helium.

Mineral Matter in Coal.—At the meeting of the Midland Institute of Mining, Civil, and Mechanical Engineers held on January 22, Dr. R. Lessing presented a paper on the distribution and nature of mineral matter in coal. This is a paper of great importance.

Westmorland Minerals.—At a meeting of the Manchester Geological and Mining Society held last month, Vincent Bramall read a paper on the minerals found in the neighbourhood of Appleby, Westmorland, with special reference to barytes.

Canadian Gold and Silver.—At the meeting of the Royal Statistical Society held on February 15, J. Bonar read a paper entitled: The Mint and the Precious Metals in Canada.

Yampi Sound Iron Ores.—The *Queensland Government Mining Journal* for December contains an abstract of a report on the Yampi Sound iron ore deposits, northern West Australia, made for the Queensland Mines Department by C. F. V. Jackson and E. A. Cullen.

Salt Manufacture.—In *Chemical and Metallurgical Engineering* for February 2, W. L. Badger describes the salt deposits of Michigan and the method of raising the brine and manufacturing salt.

Non-Metallic Minerals in the United States.—In the *Engineering and Mining Journal* for January 29, R. B. Ladoo gives an account of the production of non-metallic minerals in the United States.

Fluor-Spar. — In the *Engineering and Mining Journal* for January 29, J. M. Blayney describes the mining of fluor-spar at Fairview, Illinois.

East Indian Topography. — The *Geographical Journal* for February contains a paper by G. A. F. Molengraaf on modern deep-sea research in the East Indian Archipelago. The paper contains much matter useful to the geologist interested in Eastern tin deposits.

Hydro-Electric Power in Wales.—In the *Engineer* for February 25, J. B. C. Kershaw gives an illustrated account of the hydro-electric installations in North Wales, in being and contemplated.

RECENT PATENTS PUBLISHED.

☞ *A copy of the specification of any of the patents mentioned in this column can be obtained by sending 1s. to the Patent Office, Southampton Buildings, Chancery Lane, London, W C 2., with a note of the number and year of the patent.*

16,719 of 1919 (157,487). H. S. POTTER, Johannesburg. A hammer drill with a reversible hammer piston and rotating device modified accordingly.

18,038 and 19,797 of 1919 (157,490). W. BROADBRIDGE, E. EDSER, and MINERALS SEPARATION, LTD., London. Agitation method for removing substances such as fats from emulsions.

18,498 of 1919 (158,010). JOHN THOMPSON, LTD., and H. E. PARTRIDGE, Wolverhampton. Method of coating iron and alloys of copper with aluminium.

21,188 of 1919 (156,852). W. L. MCLAUGHLIN, Decatur, Illinois. In grinding and pulverizing machines consisting of cylinders containing rods, the use of rods of varying diameters, whereby the interstitial spaces are reduced.

23,960 of 1919 (156,866). E. A. ASHCROFT, London. Treatment of complex sulphides with chlorine to make chlorides, and the treatment of these chlorides with magnesium or alloy of magnesium and lead or zinc for the production of metallic zinc and lead and magnesium chloride; the latter is electrolysed to recover the magnesium and chlorine.

24,767 of 1919 (157,523). C. M. CONDER and G. T. VIVIAN, Camborne. Improved vibrating screen.

24,936 of 1919 (133,716). DORR COMPANY, New York. In thickening tanks, arrangements whereby the solid settled materials are forced upward and discharged at a point near the top of the tanks.

25,544 of 1919 (157,554). P. A. MACKAY, London. Making lead sulphate pigment by treating galena with fuming sulphuric acid.

25,546 of 1919 (157,555). P. A. MACKAY, London. Recovering vanadium from vanadate of lead by treating with fuming sulphuric acid, thereby obtaining a soluble sulphate of vanadium and an insoluble compound of lead.

26,332 of 1919 (146,919). ARMOUR FERTILIZER WORKS, Chicago. Electric furnace for producing aluminium nitride.

26,542 of 1919 (156,944). T. L. GALLOWAY, Campbelltown, Scotland. Portable magnetometer, (described in the MAGAZINE for December).

26,570 of 1919 (157,576). S. HARE, Bishop Auckland. Improved method of mounting coal-cutters to enable them to work a wider track.

26,985 of 1919 (156,367). UNIVERSAL COAL MACHINE CO., Boston, U.S.A. Improved tunnel-boring machine.

28,091 of 1919 (135,199). C. L. STICKNEY, Skull Valley, Arizona. An expanding bit for use in rock-drills, having for its object the widening of the drill-hole at the bottom into a chamber to take the charge of powder.

29,417 of 1919 (156,971). Y. NISHIZAWA, Tokyo, Japan. The addition to white sulphide pigments of organic hydroxyl compounds, with the object of preventing the pigments turning yellow.

30,613 of 1919 (136,177). GEBRÜDER EICKHOFF, Bochum, Germany. Improved compressed-air motors for jigging conveyors.

30,930 of 1919 (156,396). W. W. HOOVER and T. E. BROWN, New York. Distilling oil from shale in situ, by fracturing the shale by explosives and circulating a heating medium through it.

31,661 of 1919 (136,831). SOCIETA MILANESE IMPIANTI INDUSTRIALI CORTESE-CRESPI-SQUASSI, Milan, Italy. A rotary pulverizer for minerals.

1,267 of 1920 (156,414). TAYLOR-WHARTON IRON AND STEEL CO., Highbridge, New Jersey. Improved teeth for the edges of excavator buckets.

5,192 of 1920 (158,154). S. O. COWPER-COLES, London. Improvements in drums used in the sherardizing process.

5,227 of 1920 (139,219). J. E. KENNEDY, New York. Improved mounting for the shafts of gyratory crushers.

15,775 of 1920 (144,710). GRAF SCHWERIN AKTIEN GESELLSCHAFT, Berlin. Improved method of separating substances by electro-osmosis.

16,521 of 1920 (147,546). FRIED. KRUPP AKTIEN GESELLSCHAFT GRUSONWERK, Magdeburg, Germany. Improvements in magnetic separators.

16,533 of 1920 (145,444). L. MALECOT, Grand Croix, Loire, France. Classifier for coal and other minerals.

33,450 of 1920 (156,475). H. S. POTTER, Johannesburg. Improved rotatable chuck for steels of hammer-drills.

NEW BOOKS, PAMPHLETS, Etc.

☛ Copies of the books, etc., mentioned below can be obtained through the Technical Bookshop of *The Mining Magazine*, 723, Salisbury House, London Wall, E.C.2.

Quin's Metal Handbook and Statistics, 1921. Compiled by L. H. QUIN. Price 5s. net. Published by the Metal Information Bureau, Ltd., 7, East India Avenue, London, E.C.3. This is the eighth yearly issue of a statistical publication which is invaluable to all interested in the output and sale of metals and minerals. The advertisements form a useful feature of the book, for they convey a good deal of information with regard to the marketing of metals and the metal trade, and will be continuously helpful to the producer and buyer.

The Mining Manual and Mining Year-book, 1921. By WALTER R. SKINNER. Price 20s. net. Published by W. R. Skinner, 11 and 12, Clement's Lane, and *The Financial Times*, 72, Coleman Street, London. This is the 35th annual volume of the standard reference book relating to mining companies registered in this country and companies registered abroad that are known among English investors.

Cobalt, 1913 to 1919. Pamphlet published by the Imperial Mineral Resources Bureau. Price 9d.

Antimony, 1913 to 1919. Pamphlet published by the Imperial Mineral Resources Bureau. Price 1s.

Mining and Preparing Domestic Graphite for Crucible Use. By G. D. DUB and F. G. MOSES. Bulletin 112 of the United States Bureau of Mines.

Bolivia's Case for the League of Nations. By JOSE CARRASCO. Published by Selwyn & Blount, 21, York Buildings, Adelphi, London, W.C.2.

Manufacture of Sulphuric Acid in the United States. By A. E. WELLS and D. E. FOGG. Bulletin 184 of the United States Bureau of Mines.

Crystallography ; A series of Nets for the Construction of Models Illustrative of Simple Crystalline Forms. By JAMES B. JORDAN. Price 3s. London: Thomas Murby & Co.

Exploitation du Pétrole par Puits et Galeries. By PAUL DE CHAMBRIER. Paris: Dunod, 47 and 49, Quai des Grands-Augustins. A paper based on this pamphlet was read at the February meeting of the Institution of Petroleum Technologists.

Geothermal Data of the United States. By N. H. DARTON. Bulletin 701 of the United States Geological Survey. In this volume are collected all the available records of earth temperatures in the United States, together with many original investigations.

Refractory Materials : Fireclays, Resources and Geology. Paper covers, octavo, 250 pages, illustrated. Price 8s. net. This is vol. xiv. of the special reports on the mineral resources of Great Britain prepared by the Geological Survey. The volume contains a brief but comprehensive account of the geology of the fireclay deposits of Great Britain, with special reference to those beds which are at present employed for the manufacture of fire-bricks, furnace-linings, and other refractory materials. The industry is an old-established one, and, especially during the war, was of great national importance. The British fire-clays are described according to the counties in which they occur, and particulars are given of every deposit that is known to be of economic value. Fortunately for the country there is an abundant supply of fire-clay, and the reserves are large, while the variety of clays is such that almost every use to which the mineral is put can be adequately provided for from home sources. The volume is a sequel to the Memoir on Silicious Refractories previously published, and it is intended to issue another part containing chemical analyses and furnace-tests of many of the best known fire-clays.

COMPANY REPORTS

Taquah Central Mines.—This company was formed in 1909 to acquire gold-mining claims at Tarkwa, West Africa. Bewick, Moreing & Co. and the Taquah-Abosso group were interested. The property was being developed in 1912 when the workings were flooded. As recorded last June, the mines are being reopened, £60,000 of new capital having been subscribed. Bewick, Moreing & Co. have retired from the general managership, and the management has been transferred to the Taquah Mining & Exploration Company. The report now published covers the year ended June 30 last. This shows that work was resumed in July. The surface plant has been reorganized and additional plant supplied. The present development work consists of making connection between two adits 2,000 ft. apart. When the pumps are going, development will be undertaken on the 400 ft. level. The labour position in this district is improving.

Geevor Tin Mines.—The report of this company, which operates tin mines near St. Just, Cornwall, covers the year ended March 31, 1920. During this period 28,324 tons of ore was treated, yielding 432 tons of tin concentrate, being an average of 34·16 lb. per ton. The amount received by the sale of this concentrate was £69,064, or £159. 17s. 5d. per ton. After allowing for depreciation and writing off a proportion of development and shaft-sinking, the balance of profit was £6,256, which was carried forward. In our issue of December, 1919, details were given of the increase in capital for the purpose of extending operations; during the period covered by the present report £21,407 was spent on this extra development and £17,605 on additional equipment. Last summer further capital was issued for the purpose of acquiring control of Levant. The present position at Geevor is that mining is suspended owing to the low price of tin. Further particulars are given in the Review of Mining.

De Beers Consolidated.—This company has been working diamond mines near Kimberley, Cape Province, South Africa, since 1888. The report for the year ended June 30 last shows that 1,927,178 loads of diamond ground was raised at the Wesselton mine, 2,021,026 loads at Bultfontein, and 1,796,573 loads at Dutoitspan, making a total of 5,744,777 loads. The amounts of weathered ground washed at these mines were 1,646,895 loads, 2,251,895 loads, and 1,892,558 loads respectively, making a total of 5,790,710 loads. The respective yields per load were 0·24 carat, 0·29 carat, and 0·16 carat. As already recorded, disintegration by weathering is being abandoned for mechanical breaking, as adopted at the Premier diamond mine. The accounts show a mining expenditure of £1,991,258, and other expenditure £741,976. The credit for sales of diamonds was £6,761,840, and interest and dividends brought the total revenue to £6,997,899. The profit was £4,264,665, out of which £439,550 was paid as taxes, £800,000 was paid as preference dividend, and £3,000,000 as ordinary dividend, the rate on the preference shares being 40% and on the ordinary 120 per cent.

Exploration Company.—The report of this company for 1920 shows a gross profit of £74,599 and a net profit of £57,162; £20,000 has been written off for depreciation, and £37,500 has been distributed as dividend, being 10% tax paid. The low American exchange during the early part of 1920 made it profitable to sell nearly all the company's investments in the United States. At the meeting of shareholders, the chairman, R. T. Bayliss, spoke very hopefully of the prospects in Mexico and recorded his desire to increase the company's business in that country provided suitable properties came before his notice.

FUEL composed of a mixture of oil and coal dust is being tried in locomotives on the Great Central Railway with encouraging results. Experiments are now being conducted with a view to perfecting the burners and combustion chambers. The reports indicate that this type of fuel is easier to handle than coal dust.

IT will be remembered that recent efforts of the Institution of Civil Engineers to protect the term "civil engineer" failed owing to the difficulty of dealing with engineers who were not members of the Institution but were nevertheless of high professional standing. The Institution is now applying to the Privy Council for a supplementary charter to enable it to confer the title "chartered civil engineer," which shall be recognized as a mark of professional civil engineering status. Members of other societies will no doubt make the necessary inquiries so as to ascertain how this proposal will affect them.

THE removal of gases dissolved in water, especially oxygen, is nowadays receiving the close attention of chemists and other engineers. The Crowe vacuum treatment in cyaniding is one example of this line of research and improvement. Another example is found in the similar method of softening water for boilers and other chemical and mechanical applications. The removal of oxygen may be effected by heat, vacuum, or chemical reaction, and the relative advantages of the methods may be tested for each individual application. Readers interested in this subject should study a paper by Mr. Paul Kestner, presented to the Institution of Mechanical Engineers and the Society of Chemical Industry last month, and another paper by Mr. H. A. White, published in the December *Journal* of the Chemical, Metallurgical, & Mining Society of South Africa. Exigencies of space have prevented us from giving fuller notice of these papers.

LORD Moulton, who died last month, was in many ways a remarkable man, whether considered as a mathematician, scientist, administrator, or lawyer. Perhaps his greatest service to the country was done as head of the explosives department of the Ministry of Munitions, where, in conjunction with Mr. Kenneth Quinan, he impressed the true requirements of the country upon the military authorities and the politicians, and forced the expansion of production. He shone less as a lawyer than as a scientist, for the miserable insincerities of patent litigation have the tendency of narrowing a man's mental process. Science lost a powerful exponent when Moulton became an expert in patent law.

LELAND Stanford University is about to establish a research institute for the study of the problems of the production, distribution, and consumption of food, and it is proposed that the institute shall bear the name of Mr. H. C. Hoover, who has deposited with his alma mater an enormous amount of documentary material on these subjects, accumulated during his work in connection with the Belgian Relief Fund and also as Food Controller for the United States. A large measure of financial support for the institute will come from the Carnegie trustees.

THE destruction of marine life by oil discharged from ocean-going and other ships continues to receive the attention of various authorities around the coast. The Kent and Essex Sea Fisheries Committee, at a meeting held last month at Fishmongers' Hall, had much to say on this subject. It was stated that at times the surface of the lower reaches of the river and even the sea off Southend are covered with oil, which settles on the flats at low tide. The fishermen who used to make a good living between the Essex and Kent coasts are giving up their operations owing to the detrimental effect of oil on the young fish.

THE holiday course in economic geology held in connection with the Camborne School of Mines last summer was a great success, for students, young and old, were attracted from all parts of England. Preparations are now in hand for a similar course during the coming summer, the period to be occupied extending from July 18 to August 27. On two days every week there will be lectures and laboratory work dealing with rocks and rock-forming minerals, veinstones in the hand specimen and thin section, and mechanical analysis of alluvial sands and dressing products by vanning, magnetic, electrostatic, and flotation methods and by means of heavy liquids. One day a week will be devoted to the detailed mapping of a small area on surface and underground. On one day a week there will be a short local

excursion, and on another day every week a longer excursion, occupying the whole day. These longer excursions will be to St. Just and Land's End, and to St. Ives and Zennor, where contact metamorphism and mining methods will be studied; to St. Austell district, in order to visit china-clay properties; to Carnmenellis, south of Camborne, where granite is quarried; to the Porthleven district to study intrusions; and to the Lizard, to study Pre-Cambrian rocks. Those desirous of attending the course should communicate with Mr. E. H. Davison, lecturer on geology at Camborne School of Mines.

ANNUAL meetings of the Canadian Institute of Mining Engineers, now the Canadian Institute of Mining and Metallurgy, have a widely established reputation on account of the keen interest shown in the discussions and the good fellowship of the social sessions. The Montreal meeting of 1921, held from March 2 to 4 inclusive, was fully up to the past standards of the Institute. Notable papers were read dealing with the newly discovered petroleum fields of the Mackenzie River basin, the necessity for a more active development of the coal and iron industries of the Dominion, and other matters of national and imperial importance. Reference to some of these papers will be made in due course in the Mining Digest. At the dinner, General Sir Arthur Currie, the new head of McGill University, was among the speakers. He referred feelingly to the last previous meeting of the Institute that he had attended, a session organized behind the fighting lines in Flanders during the dark winter of 1916. Much has happened since then, and while perhaps not all the swords have been turned into ploughshares, it is a pleasure to record the general satisfaction felt at the conversion of this well known general into the Principal of McGill University.

The Mineral Resources Bureau.

Judging by the second annual report just issued, the Imperial Mineral Resources Bureau appears to have got into its stride. It enjoys the advantage of the assistance and advice of all the Governments of the Empire, of every technical and scientific society devoted directly or indirectly to the consideration of problems relating to metals and minerals, and of a great many of the big mining and manufacturing companies. The multitudinous consultative committees are composed of acknowledged experts on their own particular subjects. The list of Government representatives and representatives of societies, together with the list of members of individual committees, should give confidence in the work of the Bureau and its future. We would wish, however, to see the services of the permanent staff acknowledged in the report in greater detail. As it is, the only men giving all or a large share of their time to the service of the Bureau that are mentioned in the report are Sir Richard Redmayne, the Chairman of the Governors, and Major Henderson Scott, the general secretary. There are surely others who deserve public recognition.

As regards the publications issued by the Bureau, it is to be noted that the various reports commence with the year 1913, and the first issue of each series covers the years 1913 to 1919. Subsequently the issues will be made yearly. The subjects covered by the reports already published are: Arsenic, Bismuth, Felspar, Borates, Fuller's Earth, Magnesite, Chrome Ore and Chromium, Nitrates, Monazite, Asbestos, and Zinc. Reports on Cobalt and Aluminium may be expected any day, and others nearly ready for publication deal with Manganese, Copper, Coal, Lead, Phosphates, Fluorspar, Talc and Mica, Vanadium, and Barium. Those in course of preparation deal with Tungsten, Gold, Titanium, Platinum, Tin, Silver, and Nickel. The collection of statistics and records is always a difficult matter, even under the most favourable auspices, but the period 1913 to 1919 gives particular trouble owing to the incidence of the war. Hence the delay in publication and the incompleteness of some of the statistics. To give an idea of the range and scope of these reports, it is convenient to examine that on Zinc, the most recently published. This report was prepared by the staff of the Bureau and passed by Messrs. J. C. Moulden, H. M. Ridge, and H. Livingstone Sulman, the Bureau's technical committee on zinc. It consists of 112 pages. The first chapter deals with the ores and methods of extraction, the uses of zinc as a metal, in alloys, and in compounds. Then a general review is given of the world's production, with tables of yearly production of zinc and ores in each country. The countries are then taken seriatim, firstly the constituents in the British Empire and afterward foreign states. Full statistical information is given, and the principal producing centres are briefly outlined. Afterward comes a bibliography of books, articles, and papers on zinc, a truly valuable feature of the report. Finally there is a review of the metallurgical industry in connection with zinc as at the end of 1919, written by Mr. Gilbert Rigg, of the Broken Hill Associated Smelters.

The Bureau has in hand a special and comprehensive work on the Iron Ore Resources of the World, the preparation of which was undertaken at the suggestion of the National Federation of Iron and Steel Manufacturers. The sections devoted to Spain, Portugal, Norway, Sweden are under the general editorship of Professor Henry Louis. Mr. E. O. Forster Brown is supervising the sections dealing with France and North Africa, and Dr. F. H. Hatch the section on the ores of the United Kingdom.

As regards the future of the Bureau, it is legitimate to express a hope that the energies now displayed without adequate supervision by the Imperial Institute in the publication of general reviews of subjects connected with metals and minerals should not be continued independently of the Bureau. Before the Bureau was founded, some doubts existed in many quarters as to the advisability of the step being taken, the view being that the organization already existed at the Imperial Institute. Under the conditions now existing, such critics are inclined to advise the Imperial Institute to hand over this department of its work to the Bureau. Another point to which reference may be made is the establishment of records of commercial reports made on mining districts and individual properties. This MAGAZINE attempted to establish a register of this sort some years ago, but engineers generally felt that the enterprise should not be in the hands of a privately owned company. Such a register would be of great value to people contemplating the development of mineral deposits, and it is possible that the Bureau could undertake its formation. We make the suggestion for what it is worth.

Mining at Great Depths.

The discussion on Mr. E. H. Clifford's paper on the new shaft at City Deep, read in February before the Institution of Mining and Metallurgy, was continued at the March meeting, on which occasion Dr. Leonard Hill gave a helpful and illuminating address on various points connected with the physiological aspects of the problem. Indeed, the whole discussion at both meetings has turned on the consideration of this side of the question rather than on the mechanical features involved in the design of the shaft and plant. As mentioned last month, Dr. Leonard Hill is a physician who has made a special study of ventilation, heating, and cooling in relation to their influence on human comfort and capacity for work, and it was a happy thought on the part of the Council of the Institution to invite him to take part in the discussion. They have also invited him to write a paper for the Transactions, which will in all probability be read at the meeting in October. We can see in the future Dr. Hill giving valuable advice to the exploiters of deep metal mines, when the physiological factor becomes increasingly predominant.

One or two points in connection with the physiology of mining other than the reduction of heat and moisture were discussed at the meeting and deserve attention. In the first place Mr. Bernard Holman, of the Royal School of Mines, mentioned the ill effects caused by the absorption of nitrogen from the air into the blood while working under considerable air-pressure. This nitrogen is apt to be liberated from the blood with fatal effect if the pressure is reduced too rapidly, and thus there may be danger in bringing the men to the surface at the usual speed of a winding engine. This nitrogen danger is well known in diving operations, though the average man in the street is, of course, not aware of its existence. In the operations for the salving of the gold on board the Laurentic, which sunk in Lough Swilly during the war as a result of torpedo attack, the divers can reach the bottom at 20 fathoms in half a minute without discomfort, but fully half an hour must be allowed for bringing them to the surface again. The same precaution is necessary in connection with caisson work, where intermediate chambers are provided for gradually reducing the pressure so that the excess nitrogen shall be liberated without harmful effects to the worker. This question of relative absorption of the constituents of the air by liquids arises also in the system of compressing air by falling water, and transmitting to the point required for its use while absorbed in the water. When this method of compressing was adopted at mines in Canada ten years ago it was found that the air discharged from rock-drills would not support combustion of the lamps or candles and that this form of compressed air was therefore not ideal for the worker. It was discovered on examination that less of the dissolved oxygen was liberated than of the nitrogen, with the result that the released air was deficient in oxygen. Reverting once more to the effect of the compressed atmosphere in deep mines, it must be remembered that the surface of the Rand is 5,000 ft. above sea-level, so that at the bottom of City Deep shaft the workings will only be 2,000 ft. below the sea. Thus the air-pressure in the bottom workings will not be anything out of the way, and the nitrogen effect need not be considered. Dr. Hill, indeed, expressed his opinion that the

nitrogen effect will not arise at any depth to which a mine is likely to be sunk. Nevertheless depth in its relation to rapidity of hoisting cannot be eliminated entirely when considering these questions.

In the discussion, Dr. Hill also referred to the investigations at present being made into the causes of silicosis in the mines of the Rand. This disease of the lungs is attributed to the effect of minute sharp particles of silica, which settle on the surfaces in the lungs, and which cannot be removed in the ordinary course by the action of the lungs. The difficulty arising out of this interpretation is that the same effect is not noticed in other metal mines where quartz ores are worked. The present tentative explanation is that it is only when the quartz particles are unaccompanied by the dust of other minerals that silicosis starts; that is to say, the other minerals which are more easily removed carry the quartz spicules with them. Thus schists, shales, and igneous rocks of the wall-rocks at other mines act as preventatives of silicosis, but where foot and hanging walls are quartzite there is no constituent of the dust to counteract the effect of the silica of the ore. It has been suggested that a cure may be obtained by introducing shale or coal dust into the air of the Rand mines in order to render the silicious dust innocuous. It might also be possible to make use in some way of the rock of the diorite dykes for this purpose. The study of these phenomena is now in hand, and some definite results should be forthcoming before long. We are looking forward also with interest to Dr. Hill's paper to be read in October next. By that time he will have had the opportunity of applying his principles and methods to the particular problems of mining, and no doubt many valuable hints and suggestions will result.

Iron Ore and Greenstone.

During the last few months a number of articles and letters have appeared in our pages by Mr. J. D. Kendall and others, and in these communications much has been said relative to the origin of the iron ores of Cumberland and elsewhere. Mr. Kendall's evidence is helpful, for facts known many years ago, but not now available owing to the exhaustion of the particular mines, have been put on record, and interpreted in the light of modern theories of ore deposits. Geologists therefore have reason to thank Mr. Kendall for his articles. In the present issue Mr. J. H. Goodchild comes forward with a suggestion with regard to the origin of these iron ores which involves an entirely new conception with regard to the building of the earth. Mr. Goodchild's ideas call for a new method of examining geological and mineralogical occurrences, and a new interpretation of both the old and new facts. It is not easy to follow his statements and arguments. Like Einstein's theory, they are in the nature of an endeavour to grasp and enunciate some better explanation of various phenomena than has been available hitherto, and the resources of language wherewith to express the ideas are limited. They are as subversive of the current dogmas of the stratigraphist as these dogmas were of Genesis. Instead of expanding on his views from a general standpoint, we may raise the specific case of the greenstones occurring in association with hematite. It is usually supposed that greenstones are igneous rocks which have been extruded from below while molten. In years gone by the Cumberland hematite was also reckoned by many to be of igneous origin, but nowadays the solution theory is universally held. It usually happens in these occurrences that the contact between the greenstone and the country rock and hematite shows no sign of metamorphism, so the question arises whether the greenstone really had an igneous origin. This doubt once raised, it becomes necessary to re-apply from a different point of view the theory of Van Hise and Leith, according to which the Lake Superior hematites have been formed by the decomposition of iron silicates such as greenalite. Is it not feasible, asks Mr. Goodchild, that during this decomposition a concurrent formation of greenstone should take place? This question opens up a new line of thought, and should not be too hastily answered. To carry Mr. Goodchild's views a little further, it may be said that he questions the so-called igneous origin of many rocks, and that he doubts the separate creation of certain rocks and their enclosures, holding that in many cases both rock and enclosures have been formed at the same time. There are many other phases of rock and ore formation that might be discussed from the new point of view, but we leave readers to study Mr. Goodchild's letter. In his concluding paragraph he asks permission to return to this subject later. We give him not only permission but every encouragement to do so.

Adventures in the Desert.

The parched lands of Australia were never the ideal hunting ground for the prospector, and the records of travellers and explorers show an unbroken story of privation, thirst, or fire. Though the country is now better known, and improved means of communication exist, un-

toward events are still happening from time to time. It was hoped by many that the advent of the motor car would entirely eliminate the dangers, but motor cars occasionally go wrong, and misinformation and miscalculation may put even a Rolls-Royce out of action. We are reminded once more of the perils of the desert by the receipt of a letter from friends in West Australia, who have sent us an account of their terrible experience due both to scarcity of water and to bush fires. The writers of the letter, like average Englishmen, do not shout of their troubles from the house tops, so in recounting their experience we shall refer to them anonymously. Suffice it to say, then, that early in January a party, consisting of three engineers and the young son of one of them, left Perth for Ravensthorpe, a distance of nearly 300 miles in a south-easterly direction, travelling across the country by motor car. The journey out was successful, and after the business in hand was completed, the return trip was commenced. For the sake of variety they decided to travel by a newly-cut track, which was described as bumpy but safe. The road proved to consist for most of the way of heavy drift sand, and it was necessary to go at low gear. This had the effect of consuming much water in the radiator per mile, but as there are well-holes at intervals along the track the travellers were not worried. However, when the first well-hole, at 40 miles, was reached, it was found to be dry, but this fact caused little uneasiness, for it was expected that the remaining six gallons of water would be sufficient until the next well-hole, 40 miles further, was reached. After proceeding some miles from the first well-hole the catastrophe happened. In negotiating a bit of heavy sand, the car wheeled right on to a stump covered with bushes and a front axle went. There was no traffic on the road to furnish help, and the only thing to do was for the most active members of the party to tramp back the best part of fifty miles to borrow a spare axle and bring out a fresh supply of water, or to obtain some other form of relief. Two of the engineers undertook this journey, leaving the other engineer and the boy with the car. To tramp fifty miles through heavy sand with the temperature at 110° was no small undertaking. The position of the two left behind was not much better, for the short scrub afforded scanty shade, and there was only a gallon of water on which to subsist until relief arrived. But this was nothing to what followed. Before long smoke was smelt by the watchers at the car, and in an hour's time the clouds of smoke were thick. On walking to the nearest hillock they could see that the whole country was on fire, in a continuous blaze for miles. The smoke and heat gradually became more intense. The only resource was to seek the most open spot and to clear as much scrub as possible, then to trust to luck that the fire would pass round them and leave them still alive. The water-supply was severely rationed, the boy taking a table-spoonful every hour and the engineer one every two hours, though both of them felt like drinking the whole lot in one gulp. After several hours of this anxious waiting the wind changed, as it often does in Australia about sundown, and the further advance of the fire was stayed. The watchers were therefore able to lie down and sleep. In the meantime the other two engineers had plodded on their weary way, often only able to walk a quarter of a mile and then rest for a few minutes. This they did continuously for twenty-four hours, covering during this time 46 miles, mostly in heavy sand. Then they espied a farm-house in the distance, so they drank up their remaining water and lay down to sleep for an hour. On awaking they dragged themselves to the house, where they received food and drink, and help to cover the remaining distance into Ravensthorpe. Here no time was lost in obtaining a spare axle and a supply of water and other necessaries, and the two were again driven over the track to meet their watching companions once more. They arrived 40 hours after starting on the long tramp, and never was anybody more gladly welcomed. After repairing the car, the party resumed their journey to Perth, and were able to pass the fire belt in safety owing to the fire having been reduced to mere smoulderings after the change in the wind. On thinking over their adventure, the travellers were constrained to feel thankful that the car broke down when it did, for otherwise the party would have gone into the fire zone some twenty miles further on their journey. If they had done so, they would certainly have perished, for they could not have got back to water nor could they have penetrated the fire zone. Thus the breakage of the axle was a blessing in disguise. It is difficult to know whom to admire the most, the men who tramped fifty miles over the burning sands, or the boy who bravely endured his great trial without complaint. We cannot name them, nor do we refer to them pseudonymously as Boldrewood did with Starlight and Marston (though perhaps the analogy is not altogether a happy one); but they can cut this page out and frame it, and know that it contains an expression of the high regard in which they are held by a fellow man.

REVIEW OF MINING

Introduction.—We are in the midst of another calamitous strike among the coal-miners of Great Britain, brought about by the men refusing to accept the reductions in wages proposed by the masters, following on the decontrol of the industry. A month ago there seemed high hopes of a return of mining and engineering activity, owing to costs of labour, food, and clothing coming down. The new era of prosperity is once more postponed. In metalliferous mining circles the low price and lack of demand for metals have made it necessary for many mines throughout the world to close down. The big American copper producers are idle, and many of the Nigerian tin mines are either closed or working on restricted lines.

Transvaal.—In his speech at the annual meeting of the Transvaal Chamber of Mines, the president, Mr. H. O. Buckle, had a good deal to say about the failure of certain of the labour unions to adhere to their agreements with the Chamber, and appealed to the workers to maintain better discipline among themselves. He pointed out that Rand gold-mining is a declining industry, and that the success of a large part of the operations depends solely on the artificial conditions caused by the gold premium. Under these circumstances any prosperity enjoyed by the mines is really fictitious, and a sound position can only be secured by harder work and lower costs. Sir Lionel Phillips spoke in support of Mr. Buckle's expression of views, and appealed to the men to drop the frivolous frame of mind at present observable in the doings of the unions.

The Government of the Union of South Africa is cutting down public expenditure allowed to the Councils of the Provinces and is abating taxation somewhat. For instance, the Provincial tax on the gold mines is abolished. This tax is not in itself of great amount, but its withdrawal may be taken as a sign of the times.

In spite of the many well-known adverse conditions, East Rand Proprietary Mines has been able to keep going during 1920. The amount of ore milled was much the same as in the two previous years, at 1,460,000 tons, which compares with about 2,000,000 tons in earlier years. The yield of gold was 400,496 oz., selling for £2,209,536, of which about one quarter, or £527,000, came from premium, and the working profit was £192,994. A large proportion of this profit went in debenture interest and redemption of debentures. Mr. E. H. Clifford gives a comprehensive report on developments. He shows that in the bottom levels of the western section some fairly good results have been obtained, and that work in the Cason-Cinderella is promising. On the other hand, only 20% of the ore developed in the Hercules is payable. While the individual developments here recorded might be satisfactory for smaller properties, they are not considered good enough for a big concern like the present company, and the outlook accordingly continues uncertain. The reserve is estimated at 2,410,850 tons averaging 6·1 dwt. per ton, as compared with 2,634,350 tons averaging 6·3 dwt. the year before.

No. 1 shaft at West Springs has cut the reef at a depth of 3,890 ft. The samples taken of the reef averaged 2·04 dwt. over 100 inches. No. 2 shaft is expected to reach the reef in a few months' time. It will be remembered that the development of this property was commenced by means of drifts from Springs, so that work could be done on the reef without waiting for the completion of the shafts, but little information has been published relating to the results obtained.

The south-west shaft at Modderfontein B intersected the reef at a depth of 1,488 ft. The assays gave an average of 29·1 dwt. over a width of 13·9 inches.

Last month it was announced that the Daggafontein company had come to the end of its financial resources without having proved any great amount of ore. An official statement made since then says that owing to the present unsatisfactory condition of the money market it is impossible to raise further funds, so that it is necessary to suspend all mining operations. Since the reconstruction in 1916, the Consolidated Mines Selection group has provided £1,000,000 for shaft-sinking and development. When a favourable opportunity arises, additional capital will be raised wherewith to recommence development.

Adverse financial conditions have made it impossible for Modderfontein East to complete its scheme for erecting the treatment plant recently bought from the Simmer Deep and Jupiter companies. A large sum was necessary for erection of this plant, and money was also wanted for the redemption of debentures, and for an extended campaign of development. As it was found impossible to obtain sufficient money on reasonable terms, it has been decided to postpone the erection of the plant, and to continue to send the ore to the Apex mill. To pro-

vide for paying off the debentures and for development requirements, the Central Mining & Investment Corporation has advanced £400,000 at 8% on mortgage of the property for a period of eighteen months. This, of course, is only a temporary protective measure.

Proposals have been made by directors connected with the financial house associated with Luipaard's Vlei to the effect that the gold produced, or that part produced by low-grade mines, should not be sold on the market in the usual way but should be held in the country and financed by the Treasury. Mr. J. A. Cohen expressed the opinion that if all the mines could deposit their gold for two years with the Treasury against gold certificates the market price of gold could be forced up to 120s. per oz. Mr. F. H. Hamilton's proposal is that low-grade mines should deposit their gold with the Treasury during the months January to August, while the gold premium is low, the Treasury financing them during this time, and that the gold should be realized during the end months of the year, when the premium is high. Mr. Cohen's proposal ignores the facts that the high price now obtained for gold arises solely from the position of exchange banking, and that governments do not pay more than standard price for gold. Mr. Hamilton's proposal might pass if applied privately on a small scale, but in any case the charges for such banking facilities would be considerable. Moreover, the value of the certificates issued by the Treasury against the gold deposited would be influenced by the ordinary laws of exchange.

There is to be no appeal to the Privy Council by Sir J. B. Robinson against the judgments given against him in favour of Randfontein Estates by two courts in South Africa. He has paid the amount due from him, £391,000, so the incident is now at an end.

The Royal Dutch oil company is making an investigation into the oil-shale deposits belonging to the African Oil Corporation in the Wakkerstroom district of the Eastern Transvaal. Particulars of these deposits were given in the MAGAZINE for February, 1918, and November, 1920. It is confidently believed in Africa that the Royal Dutch will exercise the option and spend £500,000 on development.

Rhodesia. — The output of gold during February was 40,816 oz. valued at £288,225, as against 43,428 oz. valued at £293,794 in January. The official figures still contain no explanation of this high valuation of the gold. Other outputs in Southern Rhodesia were: Silver 10,517 oz., coal 41,409 tons, chrome ore 9,325 tons, copper 232 tons, asbestos 2,227 tons, arsenic 17 tons, mica 6 tons, diamonds 23 carats.

The strike to which reference was made last month has been settled in the way expected, that is to say, the men went back on the masters' terms, but there is still some little friction and there are questions outstanding for settlement.

The future of the government of Rhodesia still occupies the attention of the local and imperial authorities. A committee has been appointed by the Imperial Government to consider a number of questions in this connection. Lord Buxton is the chairman of this committee, and as he has only just returned from South Africa, where he was Governor General of the Union, he ought to be able to give some sound advice.

The Cam & Motor company has issued a report of the first month's run of the reorganized treatment plant. During this month (February) 8,200 tons of ore, averaging 44s. per ton, was crushed in ball-mills. Table concentration gave 989 tons of concentrate averaging £10. 9s. 6d. per ton. Of the concentrate, 751 tons was treated, yielding 1,495 oz. gold, worth £6,462 at par. The trial run of the flotation plant commenced on March 7, and the results obtained are very satisfactory.

Nigeria.—Owing presumably to the present financial stringency and the decline in African trade, the purchase by Lever Brothers of the control of the African and Eastern Corporation is not to be completed. Reference was made to this deal last October, and the consent of shareholders was subsequently recorded. The scheme, however, required the consent of the Court, and as a matter of fact the case was down for hearing just as the announcement of the abandonment of the plan was made. It was the intention of Lever Brothers to bring this corporation under the control or management of the Niger Company. The financial stringency was the cause also of Lever Brothers having to issue debentures last month. This issue did not prove acceptable to investors, and a large proportion was left in the hands of the underwriters.

The first bulletin of the new Nigerian Geological Survey, prepared by Dr. J. D. Falconer, has been issued. It deals with the general geology of the central part of the Plateau tinfields. We hope to give extracts in an early issue.

Australia.—Like all copper companies, Mount Lyell is unable to make a profit. Last month the directors had long conferences with the various Unions with a view of arranging for a reduction in wages and other alterations in the conditions of work so that the costs could be cut down. The men, however, refused to

entertain any proposals for a reduction. The Mount Morgan mine continues to be run at a loss, and the directors closed-down operations for a long Easter holiday. Conferences are now being held with the Unions with a view to finding some way of bringing prosperity back, but the prospect is not bright.

The position at Broken Hill is critical, and it is unlikely that the restricted scheme of work outlined last month will be continued for long. Wages, coal, and transport are all too high, and the prices of metals too low. It looks as if the mines would be shut down. It is probable, however, that the treatment of the old zinc dumps will be continued, for the purchasing contract made with the Imperial Government still holds good. As regards the fire at the Port Pirie smelting works, rebuilding has been postponed for the present. An account of this fire has been received by mail. It appears that the disaster originated at one of the burners of the " A " section of the Dwight and Lloyd sintering plant. A strong wind was blowing, and a burst of flame from the burner ignited the woodwork. The flames spread with extraordinary rapidity throughout the building, so quickly that the men on the floor had the greatest difficulty in escaping. The whole building was ablaze within a few minutes. Every effort was made to get the fire hoses to work as quickly as possible, but the wind was so strong that absolutely no check could be given to the flames in the main building. Work was therefore concentrated on the detached buildings surrounding the Dwight and Lloyd buildings, to prevent the spread of the fire to the power-house. So intense was the heat that the roof of the power-house was ignited several times, and gangs of men were employed with buckets and fire extinguishers in keeping down these outbreaks. The damage may be summarized as follows: Dwight and Lloyd plant completely gutted, storage bins badly damaged, conveyors badly damaged, Huntington-Heberlein section damaged but not destroyed, Ropp roaster section damaged but not destroyed, ironstone crusher badly damaged.

The political and economic position in Australia is gradually altering and the stringent legislation engendered by war conditions is already being relaxed. For instance, ores and minerals may now be freely exported, and machinery for dealing with Victorian brown coal is to be bought in Germany.

India.—Owing to the better terms obtained in the realization of gold, and also owing to the fall in the rupee, the Mysore Gold Mining Company was able to make a larger profit during 1920 than in 1919, in spite of the smaller amount of ore mined and gold produced. The 233,502 tons of ore milled compared with 270,425 tons the year before, and the total output of gold was 156,800 oz. as compared with 163,719 oz. On the other hand, the amount realized by the sale of the gold was £804,182, as against £694,317, and the amount distributed was £146,175 as compared with £61,000. It will be remembered that the capital was doubled a year ago so as to provide funds for exploration at depth, and that this new capital ranked for the dividend for the second half of 1920, so that the total return for 1920 was 25% as against 20% in 1919. As regards exploration work, no important amount of ore has been found, but the developments in the bottom of Ribblesdale's and McTaggart's sections are distinctly promising. The ore reserve is estimated at 841,000 tons, a fall of only 29,000 tons on the year. This maintenance of the figure is explained partly by the fact that, with a higher price being obtained for the gold, much ore that was previously unprofitable can now be worked to advantage.

Burma. — The position of the Mawchi Mines, Ltd., reflects the present condition of the wolfram industry. The company's stock of mixed tin-wolfram concentrate in this country has been accumulating, until in January the amount was 939 tons. In addition, there are 123 tons of separated tin concentrate and 18 tons of tungsten powder waiting realization here. Also 473 tons of mixed concentrate is in Burma awaiting shipment. It was thought best under these circumstances to suspend output, and instructions were given accordingly on January 27. The company has borrowed £108,000 on the above-mentioned products from the bankers and others. In order to satisfy the bankers and to put finances in a better condition, the directors offered £60,000 prior lien debentures last November, and of these £25,500 have been taken up. They are now offering the remainder among debenture-holders and shareholders. Mr. C. M. Euan-Smith has recently made an examination, and in conjunction with Mr. John D. Hoffmann has submitted a report on the property. These engineers write hopefully of the future, provided market conditions improve, and are against the abandonment of the properties. The company also has a controlling interest in the Kassa Mining Co., which was recently formed to acquire properties from the Niger Company, and there is still a liability for calls. The Kassa properties have been developed on a small scale, but it is considered best to suspend active operations for the present.

Cornwall.—The gloomy position with regard to mining continues without much hope for an improvement. At the meetings of East Pool and South Crofty there was considerable discussion as to pumping policies, fears being expressed that South Crofty would suffer if East Pool sealed off the old mine and concentrated its attention to Agar and Tolgus. The matter is now before the Minister of Mines, and a suitable working arrangement for controlling the underground water in the district is being sought.

Canada.—The Government is doing everything to discourage a rush to the new Mackenzie River oilfield, so as to prevent a repetition of the distressing events of the Klondyke rush. Particulars of the regulations for granting claims are given elsewhere in this issue.

The Mond Nickel Company has issued £1,300,000 new debenture stock, carrying 8% interest, for the purpose of redeeming the existing £500,000 6% debentures, for providing further working capital for the development of the company's business, for paying off loans from banks, and for the completion of the purchase of the share capital of Henry Wiggin & Co., Ltd., Birmingham.

United States.—The copper position has become so serious that many leading mines have been closed down entirely for a time. Though the output had been restricted, the stocks of unsold copper continued to accumulate, and drastic action became necessary. At present Anaconda, Utah Consolidated, Ray, Chino, Nevada Consolidated, and Calumet & Hecla are idle.

It is announced that Minerals Separation has commenced an action for breach of patent rights against the Jackling porphyry group of copper-mining companies, including the Utah Consolidated and Nevada Consolidated, and other companies using the Callow method of concentration by flotation.

Mexico.—Considerable disturbance in London oil circles was caused by the publication of a statement by Mr. Ralph Arnold in the monthly paper issued by the American Institute of Mining and Metallurgical Engineers to the effect that the Mexican oil reserves would be exhausted in a year's time and that many wells were being ruined by the inroads of brine. The houses interested in Mexican oil have published denials of Mr. Arnold's gloomy forebodings. Mr. Arnold's motives in making the statement in question were probably two-fold. In the first place it was intended as a practical reason for a protest against the policy of the chief producers in America in making such severe cuts in the prices; and secondly, there was a hope that some such statement would deter the Mexican Government from imposing a big tax on oil.

Hungary.—Toward the end of last year it was announced that the Anglo-Persian Oil Co. was negotiating with the Hungarian Government for oil concessions in that country. A company has now been formed called the Hungarian Oil Syndicate, as a subsidiary of the Anglo-Persian, with a capital of £130,000, for the purpose of making the necessary preliminary investigations.

Spain.—For the first time for more than a generation the Rio Tinto Company is not paying a dividend on its ordinary shares. The prolonged strike, and the depression in the copper and pyrites markets, have combined to bring about this result. The company is, however, able to pay the preference dividend and to carry forward a substantial amount.

Persia.—The Anglo-Persian Oil Company has made an issue of £3,500,000 9% cumulative second preference shares, and, unlike some recent industrial issues in other departments of commerce, the shares were eagerly absorbed by investors. The money is required for several purposes. The number of pipe-lines from the oilfields to the coast is being considerably increased, and many new steamers have been bought or are in course of construction. Then the company is preparing to take into its own hands the work of selling its benzine and kerosene production after the present sale contract expires at the end of 1922. The building of the refinery near Swansea has also been undertaken in view of this approaching reversion of control of the refined products.

Spitsbergen.—The yearly report of the Northern Exploration Company for the year ended June 30 last, and the proceedings at the shareholders' meeting at which the report was discussed, naturally reflected the disappointment felt by all parties that the many activities of the company have led to no practical commercial results. The much-advertised magnetite deposit has retired to the background since Mr. Selkirk reported so adversely on it. The company, however, still owns coal lands, and marble, copper, and zinc deposits of more or less value, and it is said that there are indications of oil. The central figure in the enterprise, Mr. Salisbury-Jones, has retired from the board. The Honourable E. C. Pery, D.S.O., is now managing director, and we can only express the hope that his efforts to bring the company into a more prosperous condition will meet with success.

THE OIL RESOURCES OF SOUTH AMERICA.

By HENRY B. MILNER, M.A., F.G.S., A.M.I.P.T.,

Oil Technology Department, Royal School of Mines.

INTRODUCTION.—The great and ever-increasing demand for petroleum products throughout the world has at last impressed on both producer and user of oil-fuel the vital necessity of taking stock of existing oil resources. Statistical evidence available from the United States and other oil-producing countries proves conclusively that if the demand continues to exceed the supply at the present abnormal rate, the exhaustion of several of the most productive wells extant may be expected within the next two decades, assuming that no drastic scheme of oil conservation be universally adopted in the meantime. As a matter of fact, the United States Government is fast waking up to the need for economy in this direction, and as producer of nearly 80% of the world's crude oil, any steps taken as a precautionary measure in limiting her oil exports must result in serious consequences for those countries who, like ourselves, are mainly dependent on her for their industrial requirements.

In a recent review of British and Colonial oil resources,* the writer has uttered a warning of what may be quite reasonably anticipated in the near future with regard to our home oil industries, and while disclaiming all idea of oil famine (as several press enthusiasts would have us believe), he has advocated not only rigid economy with existing supplies, but the full utilization of oil-shale and organic substances as sources of oil and, above all, renewed and unstinted enterprise in the discovery of new fields in those countries in which geological conditions are known to be satisfactory. It is with this latter phase of the problem that we are here chiefly concerned, and it is the present intention to indicate the great economic probabilities awaiting extensive development of the oilfields of South America, a continent as yet only in its infancy with regard to oil production.

It has of late years been quite customary among oil technologists to make merely passing reference to South America as an oil-producing continent, opinions being usually of a doubtful character and tempered with no little pessimism concerning climatic and political conditions prevalent there. That there are inherent difficulties attending operations in some of the most promising regions is not to be denied, but they are as nothing compared with those which confront unskilled prospecting in that country and which have done quite as much, if not more, to retard development in the past, as adverse conditions of environment. This brings us at the outset to the statement, applicable not only to South America but to all countries, that the future discovery of productive fields depends entirely on the exercise of technical skill in unravelling complex geological structures, and that it is to the stratigraphical geologist, trained in oilfield technology, that we must look for all ultimate developments worthy of the name; the day of chance as prime factor in oil-finding has passed, and necessity compels us to recognize the indisputable claims of science as its successor. It follows therefore that a brief survey of the main geological features involved must be prefatory to any consideration of the economic potentialities of the continent.

GEO-TECTONICS AND GEOLOGIC FEATURES.—South America presents to us three striking tectonic features which govern the disposition of the rocks composing the continental mass; these are (1) the Western Cordilleras or Andes, essentially the backbone of the continent, (2) the broad Archæan shield forming the Brazilian platform, and (3) the Northern Highland fault blocks constituting the Guiana mountain system. These three dominant structures are responsible for the initiation of the Amazon, La Plata, and Orinoco river systems, spreading respectively over vast plains known as the Selvas, Pampa, and Llanos. These latter unite to form one great central plain which is bounded by the main orographical lines determining the present configuration of the continent.

The Andes stretch for nearly 5,000 miles from Cape Horn to the Caribbean Sea and are made up of a roughly parallel series of mountain chains of varying trend. In the extreme south the range strikes N.W.-S.E., curving round to a N.-S. strike north of the Magellan Straits, a direction persistent to the Bolivian Andes. In southern Peru the line is again N.W.-S.E., which trend it follows to the Peru-Ecuador boundary, whence it partakes of a N.N.E.-S.S.W. direction throughout to the Venezuelan coast-line. The most easterly chain consists of short discontinuous masses of Ar-

* *Discovery*, August, 1920. John Murray, London.

chæan rocks typified by those of Cordoba and the Sierras to the east of the Cordillera Real of Bolivia. These masses are flanked on the west by a continuous belt of mountains stretching from Central Peru to Mendoza, principally composed of Silurian sediments. Further west still and constituting the Central Cordillera of the Coastal System is the main Jurassic zone of stratified sediments and intrusive igneous rocks, overlain in many places by extrusive lavas of recent volcanoes. This vast chain, which includes many of the highest peaks of the Andes, lies adjacent to the Coastal Cordillera, consisting of a mass of ancient gneisses, schists, and sediments of Archæan age; this most westerly belt is particularly conspicuous as defining the general trend of the Pacific coast-line, especially throughout the southern part of Chile and Tierra del Fuego.

The elevation of the Andes as a whole has been due to earth movements operating along lines having an approximate N.-S. trend; but the curious deflection of strike both in Peru and further south in Chile is due to the existence of an older mountain system whose dominant structure lines have not been entirely obliterated by subsequent orogenic movement. The influence of this older system is recognizable in the Archæan chains such as the Sierra de Tandil, striking W.N.W.-E.S.E., across the Atlantic margin of the Patagonian plain, and also in several of the minor flexures of the Bolivian Andes.

The Brazilian platform affords a marked structural contrast to the Cordillera just described. It is composed essentially of a great plateau of Archæan metamorphic rocks upon which rest thick horizontal masses of Palæozoic strata, with an upper covering of sandstone of undetermined geological age (though probably Mesozoic). The average height of this platform is about 3,500 ft., but in many places it is deeply incised by fluviatile action, mainly by the tributaries of the Amazon. We may regard the Guiana Highlands block as part of this Brazilian shield, only presenting a modified structure as it slopes underneath the Llanos of the Orinoco basin. The southern boundary of this basin marks not only the northern termination of this shield but also the line of division between the uniform structure of the latter and the more involved tectonics of the Orinoco basin and the Venezuelan Cordillera, which belong essentially to those of the ancient Antillean continent. This finds ample expression in the dominant strike of the rocks of Venezuela, which is in general E. 15 N.-W. 15 S., and is exemplified by the Venezuelan Cordillera especially; to this direction also the Tertiary rocks of Trinidad conform. West of meridian 64° the tectonic lines tend to swing round to a uniform N.E.-S.W. strike, which gently deflects to the main N.N.E.-S.S.W. trend of the Andes in this region near the Lake of Maracaibo. The Tertiary deposits bordering the lake also conform to this direction.

The E.-W. lines of folding exhibited by the Venezuelan rocks are referable to the main structures of the now sunken area occupied by the Caribbean Sea, and the several islands constituting the West Indies and separating that sea from the Atlantic are but the isolated summits of a mountain chain of the submerged land mass. A glance at a map of the West Indies shows immediately the parabolic form of the main structure lines affecting the disposition of the islands and of that part of the South American continent influenced thereby; they clearly consist of three main concave zones, with concavity facing west, named by Suess the Inner or Lesser Antilles zone, the Median or Greater Antilles zone, and the Outer Zone comprising the Tertiary deposits of such islands as Barbuda, the Bahamas, and Barbadoes. The flattening out of the curve as it passes through Trinidad, across the Gulf of Paria, and through Venezuela, effects, by its E.W. trend, the characteristic north-coast structures to which we have referred.

Thus the natural division of South America into "tectonic provinces," as determined by the three main orographical features with their intervening lowland topography, is a direct result of the differential earth movements which have affected the whole continental mass. We recognize in the Andean Cordillera a continuation of the great North American coastal ranges bordering the eastern margin of the Pacific basin; and to the main tectonics of that basin we can refer the present structural disposition of the Cordillera as a whole. With the Brazilian shield, on the other hand, we are considering an eastern remnant of what has been termed the Brazilio-Ethiopian continent, now submerged beneath the Atlantic Ocean. The Archæan platform of western and central Africa probably represents a portion of this ancient land, as both structurally and geologically the two areas present many features in common. Between the Brazilian shield and the Andes is the wide belt of lowland country of the savanna type which has undergone submergence during past geological epochs. In the Amazon and La Plata basins, for example, we have extensive developments of discontinuous marine and estuarine deposits laid down in an arm of the an-

cient sea separating the Pacific from the Brazilio-Ethiopian continents. The land to the north of the Orinoco is, as we have shown, structurally referable to the tectonics of Central America and the West Indies.

With this brief survey of the geo-tectonics of the South American continent before us, it is possible to appreciate to advantage the present stratigraphical appearance of its rocks, in particular the sedimentary facies which here specially concern us. It is perhaps superfluous to add that the location of petroliferous areas is in strict conformity with these main structural features, a fact not always valued at its full significance by many engaged in the task of oil-finding. We proceed to a consideration of the main oil-producing regions of the continent with reference to the several States concerned. These may be grouped as follows: The Andean States of Colombia, Ecuador, Peru, Bolivia, and Chile; the Atlantic States of Argentine, Uruguay, Paraguay, Brazil, and Guiana; and the Caribbean State of Venezuela.

COLOMBIA.—In a broad tract of country bordering the coast from Sta. Marta to the gulf of Darien and lying between the rivers Magdalena and Atrato are rocks of Tertiary age which include some valuable petroliferous deposits. A good deal of intermittent work has been carried out in the past in connection with drilling operations, but the results have hardly proved as satisfactory as the geological data would seem to indicate. Recently much more favourable reports concerning the extent and high quality of the oil of this region have come to hand, and development is now proceeding rapidly. The basin of the Sinu River is a specially favourable locality and the wells yield an oil with paraffin base and specific gravity of 0·858. Cartagena is the principal refining centre for the district and is also the port of shipment.

The Tertiary deposits of this area are folded in a N.N.E.-S.S.W. direction, conforming with the strike of the Western Cordillera. Surface indications of petroleum are very numerous throughout the area, but more especially around the Gulf of Urabia; their distribution and general disposition point to geological conditions of some complexity, particularly where the infolding of the Tertiary and Cretaceous rocks is intense.

Other areas have been prospected higher up the Magdalena, near Guamo and La Plata; these are situated in the plain between the Eastern and Central Cordillera, which consists geologically of sharply folded Tertiary and Cretaceous rocks flanked on either side by narrow ridges of Archæan gneiss. On the eastern slopes of the Andes, about 60 miles N.E. of Bogota, is located the Upia field in the basin of the Upia River, a tributary of the Meta. Few details are available concerning this field save that the oil is very pure, free from water, and has a specific gravity of 0·926.

In addition to the occurrences of petroleum noted above, there are large deposits of glance pitch or "manjak" mined at Chaparral on the Saldaño River, a tributary of the Magdalena. About 2,000 tons is exported annually from Barranquilla, for the purpose of manufacturing varnish. Glance pitch, a variety of asphaltite, is a natural desiccated petroleum product which, when free from mineral matter, is known as "manjak." The product from the Chaparral mines contains only 3% of mineral constituents.

The various fields situated in the State of Zulia (Venezuela), some of which extend into Colombian territory, will be considered in conjunction with others in that country.

ECUADOR.—The centre of the petroleum industry in this state is undoubtedly Santa Elena, situated on the north coast of the Gulf of Guayaquil and some 60 miles west of the port of that name. Here the oil is again associated with Tertiary strata composed of limestone, sandstone, and shale deposits, striking practically N.-S., parallel with the trend of the Western Cordillera in this region. There are abundant surface indications within a land radius of thirty miles of Sta. Elena, and development is progressing favourably. The oil has a specific gravity of 0·985, and is obtained chiefly by excavating the shallow trenches in the actual outcrops of the oil-bearing sand or by sinking wells about ten or twelve feet deep. Local conditions and crude methods of production have probably retarded progress in this country, but the possibilities of increased output following on careful geological survey of the fields are extremely favourable.

The Tertiary deposits of this region form a northern continuation of those of Peru, and have been assigned to Miocene and early Pliocene age. They are again found on the Island of Puna, midway in the Gulf of Guayaquil, where traces of oil occur.

In the neighbourhood of San Raimondo on the coast, natural asphaltic deposits are met with, also on Cojitambo Hill, a little to the N.E. of Cuenca. More recently oil indications have been reported from the Pastazza River district, some 130 miles N.E. of Guayaquil. Reports of oil springs from the Quito area should be taken with reserve; the conditions are unfavour-

* Redwood "Treatise on Petroleum," vol. i, p. 103. (1913.)

able to the preservation of oil-pools.

PERU.—There are several important petroliferous areas in Peru, of which the oldest and best known is that occurring as a coastal belt extending from the Gulf of Guayaquil (Malpelo Point) southwards for about 250 miles to Point Aguja. This tract of country stretches inland to the western slopes of the Cordillera, and embraces the well known fields of Negritos, Lobitos, and Zorritos. Its rocks are of Tertiary age, consisting of productive Lower Miocene shales and sands capped by clays, sands, and conglomerates of Upper Miocene and Pliocene age. The strike of the beds is N.S., curving round to N.E.-S.W., to the north of lat. 5° S., in conformity with the change of trend of the main Andean structure line at this point.

Of the three fields mentioned above, that of Negritos is probably the most important; it is certainly the oldest known, as the ruins of the ancient shallow workings from which the Incas used to collect the oil are still to be seen. The Lobitos field is a later development and comprises an area in which a number of highly productive wells have been sunk. These fields, together with that of Zorritos, are being rapidly expanded; in 1917 the estimated production of the joint undertakings amounted to approximately 2,500,000 barrels, a production which is steadily on the increase. The port of shipment is at Talara where there is also a large refinery.

Several other areas in this country are petroliferous, and mention may be made of such promising localities as Mito (Province of Jauja), La Brey in the Chumpi district (Province of Parinacochas), while a later development near Pusi, N.E. of Lake Titicaca, in the Province of Huancane, has shown the occurrence of paraffin oil of high quality. Asphaltic rocks are also widely distributed, especially in the Provinces of Luya and Tarma.

Altogether Peru seems to offer exceptional opportunities for future development, both economically and politically. As a further asset climatic conditions are particularly good, and in this latter connection we may quote Beeby Thompson, who writes as follows: "Favoured by a healthy climate, the tropical heat tempered by perennial cool southern breezes, the absence of rain and desert-like surroundings impose no hardships, and enable work to proceed in a way unknown in any other oil country. Drilling is easy and rapid, no water difficulties occur, and the light density oils are much sought after for the extraction of petrol."* Reports all tend to confirm this view, and while they often make mention of certain geological difficulties encountered in the course of prospecting for new oil-pools, such difficulties are of a purely technical character and should not prove insurmountable as the course of geological survey proceeds.

BOLIVIA. — The oil propensities of this country are as yet comparatively unknown, though from time to time reports of the discovery of oil seepages from the eastern foothills of the Andes are received. The dominant geological structures in this particular region are determined by the ancient N.W.-S.E. lines of folding which, where intersected by the later Andean movements, result in complex quaquaversal structures as yet imperfectly understood.

The most favourable area is around Santa Cruz and to the south, extending beyond the Bolivia - Argentine boundary. Many of the petroliferous indications have been located in association with Lower Cretaceous strata, and in this respect indicate that development should be cautiously prosecuted until a thorough geological examination has been made. Generally speaking this stratigraphical horizon is not commercially productive, though where intimately folded with later sediments, it may yield results of the greatest possible importance. Future geological reconnaissance will probably reveal the presence of Tertiary infoldings, a feature of the country farther south, and conditions may thus be extremely favourable to the preservation of oil-pools. Inadequate geological knowledge, coupled with the facts that the region is somewhat inaccessible and that labour difficulties are very real, have undoubtedly impeded exploration in the past, though with the ultimate development of contiguous areas in Northern Argentine (q.v.), much light should be thrown on the possibilities of the region.

CHILE.—The oil resources of Chile are at present unknown, and our knowledge of the country in this respect is largely limited to surface indications in the north, in the Province of Tarapaca, while in the Maullin River basin and in the Tertiary region to the south, natural gas is being constantly located. Some authorities speak very highly of the oil prospects of this region, and while to a certain extent this may be justified, geological conditions, at all events on the west coastal belt, are hardly satisfactory. Redwood mentions indications of oil in the Puerto Porvenir and Agua Fresca areas (Magallanes Territory), but we have little information concerning this occurrence beyond the mere statement.*

* Beeby Thompson: Oilfield Development, 1916, p. 80.

* Redwood: Treatise on Petroleum, vol. 1, p. 195

ARGENTINE. — The Argentine Republic offers many favourable prospects for the location of productive fields, especially on the eastern slopes of the Cordillera. Large areas of petroliferous rocks are known from the Provinces of Salta and Jujuy, consisting of (?) Mesozoic dolomites, sandstones, and conglomerates in which wells have been sunk with promising results. At many horizons these rocks are asphaltic, particularly in the north, near the Bolivian border. Oil shales of Rhætic age have been located in the neighbourhood of Mendoza, and to the west and south of San Raphael, while further south in the Val de Chillan similar deposits have yielded shale-oil on distillation.

Another oil-bearing region of some importance is that situate on the east coast near Comodoro Rivadavia in the Chubut Territory; this occurrence was accidentally located when sinking an artesian well in 1903, and since that time considerable progress has been made in prospecting.

The mode of occurrence of petroleum and its derivatives in this country is noteworthy; usually the oil occurs either in the form of asphalt or in the fluid state impregnating limestones and sandstones, presumably of Mesozoic age. The production is by no means uniform and a great deal of technical work still remains to be carried out. One of the most promising districts for future exploration is undoubtedly that of the eastern border of the Andes in the Province of Mendoza, where numerous seepages have been reported and examined. In some cases these have been located in Tertiary deposits, and the opinion has been expressed that the oil is not indigenous, but due to migration from underlying Mesozoic rocks. This is a doubtful point and one that requires further investigation. As already mentioned, the sedimentaries are much disturbed in this region and folding has been of a very comprehensive nature, involving both Lower Tertiary and the Mesozoic strata. The latest information shows that there are exceedingly favourable possibilities of oil production from this zone, and exploration will doubtless be watched with considerable interest.

URUGUAY.—The northern part of this country belongs tectonically to the Brazilian Highland mass, and as such presents conditions entirely unfavourable to the accumulation of petroleum. To the south and bordering the estuary of the Rio De La Plata, the country is essentially part of the Great Central Plain system, and may be expected to offer similar oil possibilities to those of the eastern Argentine, though no information of oil occurrences is generally available.

PARAGUAY.—Geologically this country is mainly a northward extension of the conditions obtaining in Uruguay. On its eastern borders it is structurally referable to the Brazilian plateau, though apparently a further element is introduced by the existence of a remnant of the ancient mountain system which can be traced particularly in the Parana basin. Westwards the savanna type of country is prevalent, and prospecting for oil has been of a very minor character, and devoid of commercial results.

BRAZIL.—The petroleum resources of Brazil must, in view of the geological and tectonic conditions, be extremely limited, and although there may be latent possibilities in the Amazon basin toward the interior of the continent, the country as a whole is entirely unsuited to oil production save for that of shale oil which has received a certain amount of attention in the past. In this respect, the bituminous deposits of the Camamu basin in the Province of Bahia have often been described and several attempts have been made to work them on a commercial scale, but so far without a great deal of success; the material is known as "turfa," and it occurs in several areas throughout Brazil, but more particularly along the coastal belt. A long tract of bituminous shale extends from the mouth of the Amazon southward to Porto Alegre, with which this occurrence in the Camamu basin is associated, but it is very impure and of doubtful economic value.

In a recent newspaper article from Rio de Janeiro, the oil resources of Brazil were painted in extremely glowing colours, particularly in connection with shale oil from "valuable deposits in the interior"; these shale deposits were reported to contain a high percentage of volatile matter, and projects on a large scale were being made to develop them. Dr. Alderson, in his book on the Oil Shale Industry (1920), mentions the Brazilian shale deposits as having yielded 44·73 gallons of oil and 19·55 gallons of ammonia water to the ton, but states that they have not been worked commercially. With practically no market for the by-products it is very doubtful whether these deposits would ever constitute a business proposition.

GUIANA.—The Highlands of Guiana are, as we have seen, tectonically a part of the Brazilian plateau, only separated from that vast mass by the basin of the Amazon. Toward the north, in British Guiana, where the land

slopes down to the Orinoco basin, a tract of Tertiary strata makes its appearance, and asphalt has been found at several horizons within this tract, especially near the coast. This knowledge has led to a certain amount of prospecting for oil, and although no important results have as yet been forthcoming, conditions are by no means unattractive, particularly in the region of the Orinoco delta and immediately to the south. The main objection to the area is that of climate; field-work and exploration generally are hampered to a great extent by the exceedingly humid conditions prevalent, and in the two wet seasons by heavy torrential rainfall.

VENEZUELA.—This country, both from the geological and economic standpoints, is by far the most interesting in South America, though partly on political grounds and partly from climatic reasons it has received comparatively little attention until recent years. Owing to the very wide interest now being shown in oil development in this republic, we will deal with it in somewhat greater detail.

We have already seen that tectonically Venezuela, at all events in the north, belongs to the ancient Antillean continent, now submerged beneath the waters of the Caribbean Sea. Along its southern borders its main structures are referable to the Guiana Highland land massif, while westwards the Andean Cordilleras constitute the main lines of upheaval and folding which, in their modified N.N.E. trend in the Maracaibo region, become involved in the main Caribbean tectonics. These fundamental features determine the natural division of Venezuela into four geographic elements, two upland and two lowland tracts; the former the Cordilleran and Caribbean Mountain ranges, the latter the Orinoco Plain and the Maracaibo Basin. The geological significance of these tectonic elements is necessarily very great, and has an important bearing on the location of petroliferous regions in the country.

In the south, a vast area of Archæan granites, gneisses, and schists, constituting the basal complex of the Guiana Highlands, extends well into the heart of Venezuela; the Orinoco Plain separating this area from the Caribbean Hills is chiefly occupied by the Llanos, and is in places densely forested, as along the edge of the Highland block. The Caribbean Hills are composed of gneisses and schists and various metamorphics (The Caribbean Series), of doubtful age, overlain by Cretaceous and Tertiary sediments in many cases in intimate association. Westwards the Cordillera divide into two main ranges of mountains enclosing a great synclinal area constituting the Maracaibo Basin and the coastal plains of Coro; here again the geology is largely Cretaceous and Tertiary formations, though around the Lake of Maracaibo itself and especially along the coastal plains to the east, the Pleistocene and Recent deposits are widely developed.

From the point of view of oil occurrence in Venezuela, we can recognize two main regions, that of the Maracaibo Basin and its tectonic extension to the east, and that lying directly to the south of the coastal Caribbean range, forming a long tract of country stretching from the Orinoco delta westwards through the State of Bermudez. In the Maracaibo region there are at least four well-known petroleum districts; the first is in the neighbourhood of Mara, Limon River basin, S.W. of the Gulf of Maracaibo. Here the oil is found seeping from the rocks near the Limon River asphalt lake; the asphalt itself is worked on a large scale, though by crude pick and shovel methods, and transported by barges down the Limon River to the Gulf for shipment. The second district is that of Bella Vista, near Maracaibo itself, and is one which shows evidence of important accumulations of oil. The third is at Sardinate, on the Sardinate River in Colombia, but extending across the Venezuelan frontier, while the fourth important area is at Colon, south of Lake Maracaibo, in the State of Zulia. Other exceedingly promising areas are known on both east and west shores of the Lake, and also in the State of Falcon near the coast. In all these cases the oil is associated with Cretaceous-Tertiary rocks, though in certain fields petroliferous Miocene deposits have been definitely located. In several of the islands bordering the north coast such as Cubagua, Margarita, oil indications are being constantly found, but no fields have as yet been conclusively proved.

The other petroliferous region in Venezuela, that flanking the southern slopes of the Caribbean Hills, is undoubtedly of great potential importance, if only the very disagreeable climatic conditions can be faced, and the risk of yellow fever be minimized. Geologically and tectonically the area is connected with the southern part of the Island of Trinidad, and evidences of oil accumulation are by no means wanting. In the Orinoco delta itself and in several places to the north, mud-volcanoes, asphalt deposits, and surface oil seeps are known. At the mouth of the Guanaco river there is situated the well known Bermudez Pitch Lake (La Felicidad), having an area of over 900 acres, with an average depth of four feet; it consists principally of very pure as-

phalt, hardened at the surface, but pierced in many places by soft asphaltic and gas exudations; it is being worked on a small scale at the present time by pick and shovel method, the material being transported by trucks to the river for shipment. Not far from this occurrence is a similar deposit in the Island of Padernales, Orinoco Delta, with an area of about 70,000 sq. yd., locally known as "La Brea." Other deposits of this nature are found in the islands of Paquero and Del Plata.

Further in the interior very little oil exploration has been carried out, though indications have been reported by numerous travellers and mining engineers. The country is densely forested in many places and the geology hidden under a thick capping of Quaternary (Llanos) deposits which, in the face of the exceedingly trying climatic conditions, do not invite prolonged investigation.

An excellent small scale geological map of Venezuela is shown in the French edition of Suess ("La Face de la Terre"), 1913, vol. iii., pt. 3, p. 1295, taken from the work of Sievers.

CONCLUSION.—From the foregoing sketch of the Oil Resources of South America, it is evident that a great deal of work remains to be done in prospecting for oil in likely regions, and in further developing fields which have already proved productive. At the present time the oilfields of Peru are obviously the most important in the continent and probably constitute on all considerations the most favourable region for future development. The republics of the Argentine, Ecuador, Colombia, and Venezuela all offer substantial opportunities for profitable investigation, since they include areas in which both geologic and structural conditions are suitable to oil accumulation. The resources of the remaining countries are in the author's opinion more doubtful. The existence of the Pre-Cambrian shield as the dominant geological factor in Brazil, Guiana, Uruguay, and Paraguay, rules out at once the chances of finding oil in commercial quantity in those countries, as the overlying sediments where present are, on the whole, extremely thin and discontinuous. In Bolivia, the structures, as far as we know anything of them at present, are exceedingly complex, and comparatively little is known of the economic wealth of the country in so far as oil production is concerned. Finally, in Chile, where the geology is mainly that of igneous manifestation in some form or other, and where the sedimentaries that do occur are nearly always associated with volcanic material, the prospects do not seem to be particularly encouraging, excepting possibly in the north.

World's Production of Petroleum.—The world's production of petroleum in 1920 is estimated at 688,474,251 barrels, against 554,505,048 barrels in 1919, according to figures collected by the American Petroleum Institute. This represents an increase of 133,969,203, or 24·2%. The estimated production in barrels by countries was as follows:

	1919	1920
United States	377,719,000	443,402,000
Mexico	87,072,954	159,800,000
Russia	34,284,000	30,000,000
Dutch East Indies	15,780,000	16,000,000
India	8,453,000	8,500,000
Roumania	6,517,748	7,406,318
Persia	6,289,812	6,604,734
Galicia	6,255,000	6,000,000
Peru	2,561,000	2,790,000
Japan and Formosa	2,120,500	2,213,083
Trinidad	2,780,000	1,628,637
Argentina	1,504,300	1,366,926
Egypt	1,662,184	1,089,213
France	—	700,000
Venezuela	321,396	500,000
Canada	220,100	220,000
Germany	925,000	215,340
Italy	38,254	38,000
Total	554,505,048	688,474,251

Of the total production in 1920 the United States supplied 443,402,000 barrels, or 64·4% of the world's output. Mexico supplied 159,800,000 barrels, or 23·2% of the world's output. The Alsatian oilfield's production appears under Germany in 1919 and under France in 1920.

Canadian Oil Regulations.—The new regulations relating to the disposal of oil and natural gas lands in the North-West Territories of Canada have been published. They supersede all previous regulations and are retroactive in effect. Permits may be issued to prospect for oil and gas over a maximum area of 2,560 acres for a period of four years. This area may be staked in not more than five blocks, for which five separate permits may be issued, requiring the installation of individual drilling outfits on each location. In the event of discovery, a lease of one-quarter of the area covered by the prospecting permit will be issued, at a rental of 50c. per acre for the first year, and $1 per acre for the second and third years. The royalty on the output is fixed at 5% for the first five years and 10% thereafter. The minimum area of a location is fixed at eighty acres, the remainder of the ground covered by the prospecting permit remaining the property of the Crown. An adequate drilling outfit must be installed on a location within two years of the date of the permit; drilling to a depth of 500 ft. must be conducted during the third year and to an aggregate depth of at least 2,000 ft. during the fourth year. Where these requirements are not fulfilled, the permit immediately lapses without the declaration of a forfeiture by the Crown.

THE APATITE-MAGNETITE DEPOSITS OF DHALBHUM, INDIA.

By E. F. O. MURRAY, Assoc.Inst.M.M.

The author gives particulars of phosphate deposits in India, which might form the basis of an extensive fertilizer industry.

THE pergannah of Dhalbhum is the most easterly of the sub-divisions of the Singhbhum District and part of the Chota Nagpur Division of the Province of Bihar and Orissa. It has an area of about 1,100 square miles, which is divided about equally into cultivated lands and jungle. The northern and southern boundaries of the pergannah run along two irregular chains of hills, while the central portion, drained by the Subarnarekha River, is traversed by the main line of the Bengal-Nagpur Railway. Few of the hills rise to a height of more than 2,000 ft., but those between 1,400 ft. and 1,800 ft. are fairly numerous. They are generally covered by sal forest of varying growth and scrub jungle, while in some parts progress is liable to be both slow and painful owing to the quantity of thorn bushes of various sorts that occur.

The inhabitants of the district belong chiefly to Dravidian stock, but while Santals and Bhumijes predominate, numerous other castes are also to be found. Judged by the average Indian standard they become fairly efficient workmen, but suffer in common with the rest of the country in the time lost in the observance of numerous feasts, festivals, and ceremonies.

The chief ores known to exist in the pergannah are chalcopyrite, apatite, magnetite, hematite, auriferous quartz, and wolfram. Other allied products of economic value include white quartz, potstones, a loose grained quartzite used as a building stone, kankar and tufa, lime, diabase, and granite.

The first geological mention of the district would appear to have been made by Voysey in 1823, but long before this considerable mining had been done by the ancients in search of gold and copper. Numerous small iron furnaces were in operation until recent times, and even now the village blacksmith in remoter parts often falls back on the indigenous ores to supplement his stock of metal. Little information as to the ancient workers is to be obtained from the present inhabitants, but it seems probable that operations were commenced by the Seraks, or lay Jains, and ceased with their expulsion. The only traces at present existing of a former civilization are to be found in occasional ruined wayside shrines built of dovetailed blocks of laterite, and some carvings in either laterite or soapstone; also agate and jasper beads either round or barrel-shaped are sometimes washed out of the soil after heavy rains.

The first attempt at mining on a modern scale was undertaken by the Singhbhum Copper Co. in 1856, but this and the subsequent Hindostan Copper Co. and Rajdoha Mining Co. all failed, though not before some development work and smelting had been undertaken. From such evidence as is now obtainable it would appear that too much money was spent on surface and not sufficient underground while such underground work as was undertaken was disseminated over a lateral extent of 16 miles and little attempt was made to prove the values of the ore-bodies in depth. Of recent years the Cape Copper Co. has acquired some of the interests of the last named, and is now at Rakha Mines engaged in proving the value of the deposits when worked by proper methods.

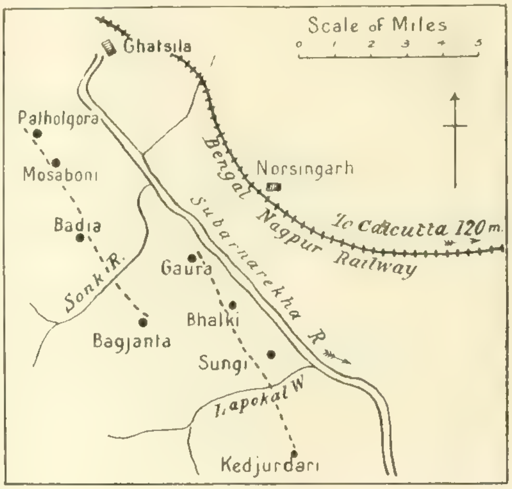
The geology of the district varies considerably in different parts, but the greater portion of the area under review is occupied by the sub-metamorphic (or Dharwar) series of sedimentaries of Archæan age, which are here represented chiefly by talc and mica schists, quartzites, phyllites, and argillaceous slates. Magnesian and hornblende schists also exist, but as in many cases these can be found grading into diabase sills and laccoliths they belong to the epoch following the deposition of the sedimentaries, though also of Pre-Cambrian age. This series of basic intrusives has its chief development just over the northern border in the district of Manbhum, where it culminates in the mountain known as Dolma, 3,060 ft. above sea level, and continues far to the west, forming some of the highest hills along the Ranchi boundary. The early diabase irruptions generally occurred parallel to the foliation of the schists, which strike roughly north-west and south-east, and usually dip toward the north. Both strike and dip, however, are subject to very considerable local variations: but in only one small area toward the north is the latter found to be southerly.

A noticeable feature is that where any large diabase irruption has occurred the surrounding schists are invariably found dipping towards it, thus pointing to their present position being the result of a subsequent uplift. The cause of this movement is to be found in the wide stretches of gneiss that exist both to the north and south of the schist belt, and though the former is outside the borders of the pergannah the portion of the southern batholith included therein covers an area of approximately 140 square miles. This gneiss would appear to have been subsequently intruded by granite dykes and laccoliths, but exposures of these are infrequent and inconspicuous when compared to the basic eruptions of a doleritic nature that later occurred. These last, which are almost entirely destitute of vegetation, vary greatly in size and strike, and are chiefly noticeable for the manner in which they protrude through the gneiss, weathering into blocks and "skulls" of all sizes.

It will thus be seen that two basic and probably two acid irruptions have occurred, any of which might have been wholly or partly responsible for the mineralization of the district. In the present case we are only concerned with the apatite-magnetite deposits, and the most likely period for their genesis would appear to be the early stages of the acid irruptions. Apatite and magnetite are both high-temperature minerals. If further proof were required as to the conditions attaining at that time it is furnished by a garnet schist band in the foot-wall and the association with the deposit of varying quantities of phlogopite mica, tourmaline, ilmenite, rutile, and hornblende.

Erosion has been very severe, as the highest hill of the district, Dolma, was itself once a deep-seated irruption, and in all cases known primary ore is found within a few feet of the surface. It seems probable, therefore, that practically all the deposits existing at the present day were deep seated and that it is only subsequent erosion that has brought them to light. In mining, this theory cuts both ways, for against the possibility of only the lower and leaner portions of some of the veins being left can be set the chance of blind lodes being yet discovered by exploration underground in the less easily eroded portions. In fact, one vein of the latter class has been responsible for practically all the gold, some 5,000 oz., hitherto produced by mining in Dhalbhum, while the quantity of lean quartz and prevalence of alluvial gold even on the lower hill-tops would point to the preponderance of the former type where gold is concerned.

The first notice of the presence of apatite appeared in 1907 (Records Geological Survey of India, vol. xxxvi.), when attention was drawn to its occurrence with some iron ore being quarried by the Bengal Iron Co. near Patholgora. Little notice was, however, paid to this at the time, and it was not until 1915 that the deposits were recognized to be of economic value. The reasons for this were the inconspicuous nature of the deposits, and the unusual colour of the mineral, which was whitish or cream-coloured and had the appearance of felspar. The discovery that this material was apatite would appear to have been more or less fortuitous, and was probably due to in-



vestigation as to the origin of the high phosphorus content of some of the pig iron made from this ore and utilized chiefly in castings. In any case work that had languished for some years and eventually ceased was suddenly resumed with unwonted vigour. This activity led to investigations, and on the cause being discovered prospecting for further deposits was undertaken. This and subsequent prospecting proved that the ore could be traced from Patholgora through Badia and the valley of the Sonk river to Bagjanta, a distance of about 7 miles, where the sequence was interrupted by a quartzite ridge striking almost due north. The probability of a fault existing here was further demonstrated by the discovery of ore about 2 miles north, near the village of Gaura or Goala, where the kyanite rock, which had been a conspicuous feature at Badia, was found to be equally prominent and to occupy the same position in the hanging wall of the

deposit. From Gaura the ore was traced with sundry breaks through Kanyaluka and Bhalki to Sungi, and thence eastwards in lessening quantity to Kedjurdari, which, as far as present knowledge goes, marks the eastern extremity of the deposits.

This run from Gaura to Kedjurdari is of the same length as the former, and though this 14 miles is only a portion of the lateral extent of the ore it would seem to contain all the deposits of economic value. The most westerly existence that has yet been found lies in the state of Kharsawan, 54 miles from Patholgora, so that it has a present known range of 68 miles ; and it is possible that deposits of value may yet be found in the portion traversing Seraikela State, where the outcrop is greatly obscured by alluvium. Parallel to the phosphate belt and at varying distances from it runs the Singhbhum copper belt, which, starting in the hills of Porahat, can be traced for a distance of over 80 miles until it is lost beneath laterite and the alluvium of the Gangetic plain.

The most important deposit of apatite would appear to be at Sungi, and as this is fairly typical of the others a description of this will suffice. The ore is found in a schist band between two beds of quartzite, which together form a ridge about 2,000 yards in length, falling away at either end where it is traversed by nallahs. The main ore-shoot is confined to the central portion of the ridge, where it can be traced almost continuously on the surface for a distance of 3,000 ft., but trenching has also exposed ore in the nallahs on either side. No definite foot-walls or hanging walls exist, the ore being found as blebs and lenses of varying size in a biotite schist belt some 30 to 50 ft. wide. The largest lens so far encountered had a length of 120 ft. with an average width of 12 ft., but owing to the irregularity of the deposit it seems doubtful whether the mean width of the entire ore-shoot would exceed three feet.

The original apatite-magnetite ore has in places been subjected to subsequent hydrothermal action, which has resulted in the original matrix being partly replaced by quartz and chalcopyrite. Small quantities of a greenish yellow uranium mineral, probably autunite, are also found locally along fissures in the ore, but this is of secondary deposition and the original uranium mineral has yet to be discovered.

The order of genesis of the minerals is distinct and divisible into 4 stages as follow:

1 (*a*) Apatite,
  (*b*) Magnetite,
2 Quartz,
3 Chalcopyrite,
4 Secondary Uranium and Copper Minerals.

Until the primary uranium mineral is found, its position in the sequence must remain uncertain, but it can probably be allocated to Group 1. Other secondary minerals include small quantities of malachite, azurite, cuprite, native copper, and bornite, but where found their horizon is limited to within about 30 ft. from surface.

The proportions of apatite to magnetite vary greatly, almost pure specimens of each being obtainable, but from samples taken the average iron content would appear to be about 20 to 25%, equivalent to almost equal quantities of apatite and magnetite by weight. When cleared of magnetite the apatite is of high grade, running over 80% tricalcic phosphate, with about 2% fluorine and 10 to 12% insoluble, but no complete analysis of the ore has yet been made.

Some trenching was carried out on the property during 1916–1917, but real work only commenced in 1918 after the flotation in Calcutta of the Great India Phosphate Co. with a capital of 30 lakhs of rupees. From rumours current about that time, hills containing millions of tons of phosphate that only required quarrying were supposed to exist, and India not being equal to absorbing the output, the company would run its own steamers to other markets, so shares went strong. Samples were sent home, a mill was ordered, and then steps were taken to develop the property. Surprises now came quickly ; the supposed quarrying proposition turned out to be really a mining one if the proposed output was to be obtained, and development had to be undertaken to assure a constant supply of ore. The mill sent out was designed for a lower proportion of magnetite than actually existed, and no allowance had been made for the treatment of run-of-mine fines, which had now to be taken into account. Eventually the company decided to liquidate, as the larger proportion of the called-up capital was still in hand.

Development work done at Sungi during this period consisted of several prospecting shafts on the lode, 2 intermediate drives east and west from one of these, and 2 adits. These last ran into harder ground than could be managed by the local hand labour and had to be suspended until a compressor and drills could be secured ; but before the former had been erected work was shut down and neither reached ore. Though the backs above these adits would only have averaged 150 ft. the lateral extent of the ore-shoot made it possible to win at least 100,000 tons, assuming that the width held, by back sto-

ping and without pumping or hoisting charges; moreover, as the exit for ore was down the valley it was desirable that this should be delivered at as low a level as possible.

In the prospecting shafts considerable trouble was experienced in following ore, owing to the manner in which lenses would suddenly cut out, and all working faces had consequently to be closely watched. At times the only method was to continue on the average dip of 45°, and to trust to one of the 50 sq. ft. of shaft hitting the next lens; but at others a quartz stringer or connecting vein of apatite served as a guide.

At present the apatite deposits, barring those at Patholgora, lie unworked. In view of the urgent need of India for phosphatic manures and the high cost of imported fertilizers, this idleness can be but a phase. The magnetite and apatite are not chemically combined, so that the only requisite is grinding to a sufficient degree of fineness to admit of efficient separation. Probably half the magnetite could be eliminated by hand picking after preliminary crushing (and a ready market exists for this product), thus leaving only some 10 to 12% of iron for removal magnetically. Even supposing complete separation to be unattainable, various methods of utilizing the phosphoric acid contents of the ore are available, but India as usual lags behind the rest of the world and seems to know little of anything but basic slag and acid phosphate, and for the latter no cheap source of acid is yet at hand. This will be remedied, however, when the Burma Corporation starts treating zinc concentrates at Jamshedpur.

IRON ORE DEPOSITS OF QUEENSLAND.

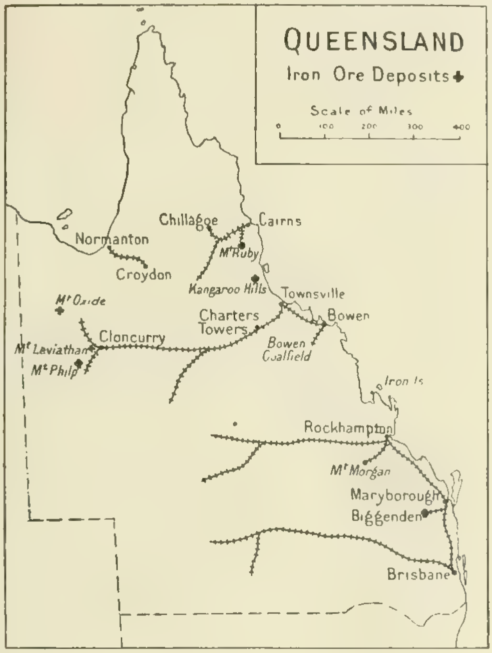
The Author of this article, who has an intimate knowledge of the Mineral Resources of Queensland, gives herewith a description of the principal iron ore deposits in that State, which are to be used in the Iron and Steel Industry about to be established by the Government of Queensland.

INTRODUCTORY.—The State of Queensland has an area of 670,500 square miles, of which over 80,000 square miles is contained in proclaimed gold and mineral fields. Scattered over this extensive mineral area are quite a number of iron ore deposits. The most important of these have been geologically examined and tested in connection with the proposed State iron and steel works, while others have been only cursorily inspected and turned down for the present as being either too small, too inaccessible, or too low in quality to justify consideration as a source of supply for these works. It is advisable to give some details of this State scheme and of the ore deposits, as many people have obtained the erroneous idea that the scheme is based on the Yampi Sound deposits off the coast of West Australia. Another reason for writing this account is that in the article in the MAGAZINE for March, 1919, on Australian iron ore resources no mention was made of Queensland deposits.

A Parliamentary Commission sat in 1917 to inquire into and report upon the advisability of establishing State iron and steel works in Queensland. As, however, little attention up to that time had been officially given to iron deposits, the evidence taken before that commission was inconclusive, and that body confined its conclusions to recommendations for the immediate erection of a furnace with a capacity of 156 tons of ore for the production of pig iron, and of extensive by-product recovery coke ovens and mine equipment, to cost £150,000, and for the appointment of a highly qualified general manager to supervise the erection of this plant and to report generally on the advisability of erecting iron and steel manufacturing works. After the issue of that report, further investigations were made by the Mines Department, a general manager was appointed who arrived in Brisbane in January, 1919, and in February of 1920 a site was determined upon for the iron and steel works, it being understood that the first portion to be proceeded with in connection with those works would be the erection of a furnace to smelt pig iron and of by-product coke ovens.

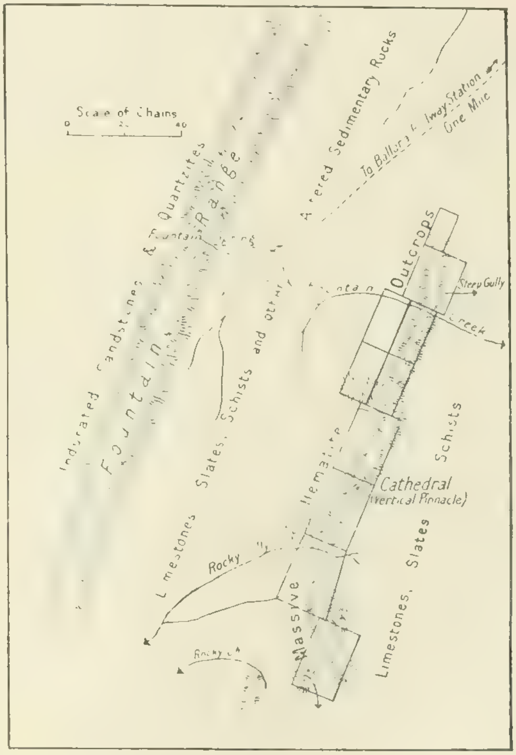
Practically, the decision to go on with these works and to fix the site at the port of Bowen seems to have been based, as far as Queensland is concerned, on the supplies to be obtained from the Cloncurry district (Mount Philp and Mount Leviathan), some 700 miles inland from Bowen, and from Mount Biggenden, in the Wide Bay district, about 500 miles south of Bowen. The deposit on Iron Island, off the coast near Rockhampton, with an estimated deposit of over 2,000,000 tons, is larger than what is expected from Biggenden (about 500,000 tons), but is probably not taken into account because it is leased to the Mount Morgan Company, which obtains its ironstone flux from there. It is probable, of course, that many more iron ore deposits will be found in Queensland, but the Government no doubt thinks there

are already enough to go on with. The present requirements of the Broken Hill Proprietary's iron and steel works at Newcastle, New South Wales, are about 260,000 tons per annum, and the general manager of that company has stated that as he can see about a hundred years' supply of ore at the Iron Knob, in South Australia, whence his works obtain it, he is not worrying about anything after that. On the same basis, the 22,000,000 tons estimated to be available in the Cloncurry district, Queensland, would



keep the proposed Queensland works going for 85 years, while another 13,000,000 tons at Cockatoo Island, in Yampi Sound, West Australia (see the MAGAZINE for October, 1920), which the Queensland Government has bought, to blend with the Cloncurry ores, will add another 50 years' supply, or 135 years in all; and it is reasonable to suppose that the Queensland Government, like the manager of the Newcastle works, is not troubling about the "thereafter." If they are, there is another possible 20,000,000 in Mount Philp that may afford a further lease of existence of over 70 years.

MOUNT PHILP.—The largest iron ore deposit in the Cloncurry district, and indeed in Queensland, is that known as Mount Philp, a comparatively recent discovery lying from two and a half to five miles south-westerly from Ballara, a railway station sixty-three miles in a south-westerly direction from Cloncurry, and 664 miles by railroad to Bowen. The Mount is a range of hills and peaks, consisting of enormous outcrops of ironstone, the adjacent rocks being altered sandstones, quartzites, calcareous and ferruginous slates and schists, with crystalline limestones and dolomites. It has been examined by Mr. B. Dunstan, the Chief Government Geologist, and is described by him in a bulletin on North-West Queensland, issued last year. Parallel with and about a mile to the west of Mount Philp is a precipitous elevation



MOUNT PHILP IRON DISTRICT.

called the Fountain Range, consisting of a narrow belt of indurated sandstone rising prominently between other soft and more easily weathered rocks. The attached sketch plan, as prepared by Mr. Dunstan, shows the position of Mount Philp and the Fountain Range, together with some of their geological features. The country on the western side of the range is said to offer natural facilities for the conservation of water.

Mr. Dunstan reports that the mountain is chiefly hematite; magnetite is occasionally present, and there are impurities consisting mostly of free silica. No place was seen in which the percentage of silica was not high, but that of other impurities in every part of the

lode tested was distinctly low. The following table gives characteristic analyses :

ANALYSES OF MOUNT PHILP ORE

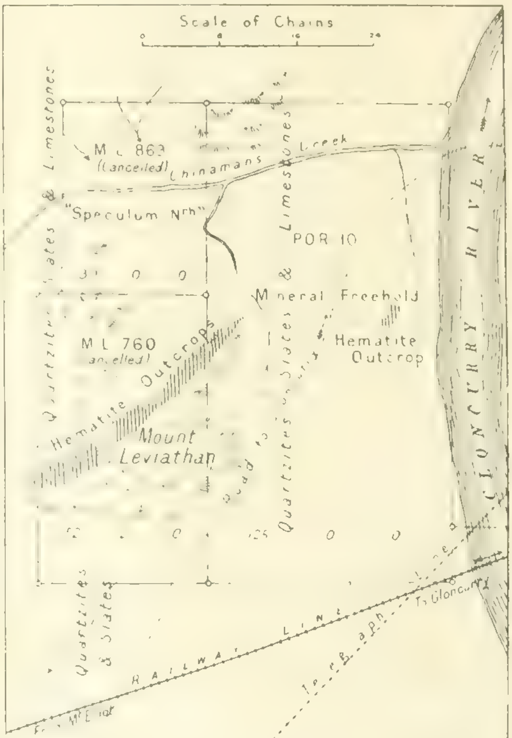
	No. 1. %	No. 2. %
Iron	56.2	52.8
Moisture (at 15 C.)	0.2	0.1
Loss on ignition	slight gain	2.3
Silica	19.5	23.0
Alumina	0.7	0.4
Lime	trace	trace
Magnesia	trace	trace
Manganese oxide	less than 0.3	trace
Phosphorus	0.023	0.03
Sulphur	0.01	0.01
Titanic oxide	nil	nil

It should be explained that analysis No. 1 is the average result from 16 samples taken from all parts of the outcrop by the Government Assayer at Cloncurry, while No. 2 was taken by the Chief Government Geologist, and was made up by sampling all the places from which the 16 samples came. Assay samples taken some years before for the purpose of utilizing some of the ironstone as a flux for copper smelting are said to have shown 17% of silica. The proportion of this impurity would appear to average about 20 per cent.

There is, judging from appearances, a great uniformity in the composition of the ironstone, and the very minute transparent silica grains present could be seen in every specimen examined. It had been suggested that the high percentage of silica might be due to the leaching out by rain of the iron from the surface outcrops, and leaving behind on the exposures an excess of silica; but Mr. Dunstan says there is an absence of porosity and that leaching effects were not apparent, a feature due no doubt to the iron oxide being in a ferric condition, the most stable form in which it occurs in nature, and apparently to the silica being in a free state, instead of in combination with basic substances.

In arriving at a rough estimate of the quantities of hematite in the Mount Philp lode, it is explained that the outcrop of that lode can be observed for miles from the top of one of the pinnacles, but that a length of two miles along the main portion contains all the measurable quantities of ore, outside of which, doubtless, there are other large quantities more or less obscured. Within this limit of two miles the lode varies from 50 to 150 ft., the approximate average being 100 ft., while the height varies from 50 to 500 ft. above the level of Fountain Creek, which cuts through the range at the north end, 150 ft. being taken as the average in this direction. Within these dimensions, Mr. Dunstan says that there must be at least 10,000,000 tons more or less under cover, making altogether an actual tonnage of about 20,000,000 tons.

As the lode has been worn down to the level of the surrounding country where Fountain Creek crosses it, and a splendid working face quite free from overburden has been naturally exposed at this spot, the facilities for working the lode can be made remarkably easy. To this face a short railway from Ballara can be very easily constructed. Farther north and south other precipitous faces are exposed at high positions, and at these places the ironstone can be quarried very cheaply and conveyed by means of shoots and other mechanical devices to trucks below.



MOUNT LEVIATHAN IRON DISTRICT.

MOUNT LEVIATHAN.—Mount Leviathan was first brought into notice as far back as 1898, when the then Queensland Government Geologist described it as "a mass, say 200 ft. high and a quarter of a mile in diameter at its base, of the purest possible iron ore." That it was not "the purest possible iron ore" was discovered many years afterward by the general manager of the Mount Elliott Copper Company when looking for a flux for use in copper smelting, and, as will be seen, its size is almost insignificant beside Mount Philp, which probably nobody except aborigines had seen in 1898. Mount Leviathan was examined at the same time as Mount Philp by Mr. Dunstan,

who gave a brief description of its geology and analyses of its ores.

The Mount is a prominent landmark just outside the town of Cloncurry, 600 miles by rail from Bowen. It forms an elevation about 270 ft. above the surrounding plains, and is a large mass of ironstone associated with quartzites, schists, breccias, and limestones, belonging to the Cloncurry (? Silurian) Series. In outline it is an irregular, lens-shaped lode, lying at an angle across the upturned edges of the sedimentary rocks, while the strike of the lode is north-east and south-west with the sediments trending north and south. A small portion of the hematite is very pure and coarsely crystalline, but the main mass contains a high percentage of silica and is frequently traversed by veinlets of quartz. Magnetite does not appear to be present in the lode, although magnetic polarity is to be observed in several places.

As showing the composition of the ore, three analyses are given in the accompanying table. The first, which is lowest in silica, is typical of the portion of the lode that is smallest in quantity, while Nos. 2 and 3 represent what may be expected to be the composition of bulk quantities.

MOUNT LEVIATHAN HEMATITE ANALYSIS.

	No. 1.	No. 2.	No. 3.
	%	%	%
Iron	62·0	56·5	57·1
Moisture	0·1	0·1	0·4
Loss on ignition	1·8	1·2	
Silica	8·9	17·0	17·5
Alumina	2·0	1·4	2·5
Lime	trace	0·2	trace
Magnesia	trace	trace	trace
Manganese oxide	trace	trace	trace
Phosphorus	0·11	0·08	0·06
Sulphur	0·04	0·05	0·006
Titanic oxide	nil	nil	nil

In forming an estimate of the quantity of ore in the lode, a cursory examination by Mr. Dunstan showed that the deposit could be divided into three sections, of which the southern part probably contains a maximum of 1,500,000 tons, and the central and southern portion about 500,000 tons, making a total of 2,000,000 tons.

MOUNT BIGGENDEN.—Mount Biggenden was worked many years ago for gold and bismuth, and in the operation of the mine considerable quantities of iron ore were proved. The Mount is 4½ miles from the Biggenden railway station, which is 54 miles from the port of Maryborough. The main deposit consists of magnetite with patches of calcite and disseminated bismuth ores. A belt of slate, 10 ft. thick, on the west separates the main magnetite outcrop from the smaller ones, while another patch has been exposed east of that in an open-cut.

One of the Queensland Government geologists (Mr. E. C. St. Smith), who was deputed to make an examination of iron deposits in view of the establishment of iron and steel works, in 1918 made an exhaustive inspection of the magnetic iron lodes of Mount Biggenden, and took a complete set of carefully averaged samples of the iron ore there. These gave the following results:

(*a*) Average sample of the whole of the ore at the main shaft dump (at least 4,000 tons) analysed: metallic iron, 59·0%; lime (CaO), 0·6%.

(*b*) The average samples obtained from different portions of the deposit ranged from 55·5 up to 64·9% of metallic iron and from a trace up to 2·8% of lime (CaO).

A general average of the medium-grade ore from the whole deposit showed the appended analysis:

	%
Water at red heat	0·3
Silica	7·7
Metallic iron	57·7
Alumina	5·1
Lime (CaO)	3·8
Magnesia	0·6
Phosphorus	0·04
Sulphur	0·13
Bismuth	0·05
Manganese	0·24

It is estimated that at least 500,000 tons of good ore can safely be relied upon as being available on this property, "with the extreme probability of a much greater tonnage being ultimately developed by exploitation."

Some of the Biggenden ore has been reduced to pig iron at the Ipswich railway workshops. The experiments were made in an unsuitable furnace and under very crude conditions, but the result was sufficient to show that the physical character of the ore, containing as it does calcite finely disseminated throughout, renders it an ideal smelting proposition as regards fusibility.

Scottish Water-Power.—The British Aluminium Co. is reviving its scheme for producing hydro-electric power from the waters of Lochs Trieg and Laggan and of several rivers in the same neighbourhood. The company is to be called the Lochaber Power Co., and the funds will be raised by the issue of 3,000,000 shares of £1 each and of £1,500,000 debentures. The proposal is now before the Secretary of Scotland. Another Scottish hydro-electric venture is the Grampian Electricity Supply Co., which provides for the erection of five generating stations and the damming of five rivers and five lochs in northern Perthshire and the eastern part of Inverness. Two of the stations will be at Blair Athol and Kingussie respectively.

LETTERS TO THE EDITOR

Cumberland Iron Ore.

The Editor:

Sir—The discussion as to the growth of hematite in Cumberland follows conventional lines. The question put is: What is the origin of the ore or what is the source of the iron? Doubtless very much more is passing in the minds of the participants than appears on paper, and therefore, feeling sure that this is so, I would suggest that the same subject matter may be treated with a different end in view. Granted that we have some fair working hypotheses as to the *origin* or history of these deposits, it may be asked what is the *meaning*, or what might be the meaning, for the world to-day of all the impressions gained during their working and study in the past fifty years.

Is it possible or desirable to continue the quest of origins any further without turning round on all the forms of thought and expression which have served for the working out of the hypotheses so far put forward? Are not accepted theories and criteria capable of improvement through the very facts of iron ore occurrence in particular? Knowledge of these facts is spread through the community; cannot it be unified for purely inductive purposes?

The criteria which Mr. Kendall uses with so much acumen have most certainly lost their hold. They derive mostly from the observation of *external* processes, such as sedimentation, erosion, etc. They miss, for the most part, the possibilities of *internal* change, and naturally so, for at the time when they were evolved such observations of internal change as those of Mr. Kendall himself had not been made.

There is no chance for rational discussion of chemistry or dynamics so long as we speak in terms of "crust." A crust in which iron ore is replacing limestone is ipso facto no crust. Of course, while we are occupied with one pocket of hematite, it is convenient to regard all the rest of the world as being at a standstill, and at every step of our observations our instincts and logical method incline our judgments in this direction.

But is the rest of the world at a standstill? The creep of the iron in its field of action, "the limestone," is but an example of simultaneous creeps the world over. Surely this world-wide field of internal change should ever be before our minds when discussing the chemistry and physics even of one pocket of hematite. As it is, we are obliged for the present to use terms borrowed from stratigraphy whose ideals are quite different. The piecing together of the "record of the rocks," the piling up of a solid crust is the stratigraphic ideal. Those parts of the structure which in the piling were least likely to change give the stratigrapher his clearest data; those parts which in the piling were most likely to change and obliterate the evidence of their origin, have changed or disappeared altogether. Hence, through the survival of stable rocks or stable configurations we are liable to take these as "normal." As it were, all the "crust" ought to be composed of fossiliferous strata, if untoward accidents did not happen (see Huxley's lectures).

But if we have neglected the less stable portions, or the factors of instability normally present in the piling up of the so-called crust, the effects of their changes incline us to infer cataclysmic processes. An ideal of a non-dynamic solid crust logically requires or leads to the inference of special disturbing forces. Fossiliferous strata being, as it were, the normal, then "igneous" action, "metamorphic" action, are discovered to be due to something abnormal to the ordered life of the land and sea.

The question at issue in Cumberland is one of internal change between chemical substances brought within range of one another at various epochs as stratigraphy indicates. The infiltrationists, I understand, take this view and probably most of them have much more in mind than the mere trickling downwards of ferruginous waters. Mr. Kendall's remarks about the breccia and the included pieces of hematite are not very convincing on paper, though in the field they might have a good deal of force against simple infiltration. "Angular" pieces may be replacements, and experience suggests that a "breccia" might well contain sporadic replacements, so sensitive do the processes involved seem to be. In any case the larger question of interaction between the components of "sediments" remains the same. Mr. Kendall, however, connects the ore with the greenstones, the "volcanic" rocks, and, as is well known, hematite and greenstone do occur together almost universally. Suppose then that the greenstone is also a product of *internal* change, and does not come from *inside* the "crust;" what then? Suppose normal inclusions of salt, etc., unstable elements in crust-*building*, led to the *growth* of greenstones?

Returning to the opening sentences of this letter, I suggest that the two hypotheses preferred by Mr. Atkinson and Mr. Kendall are, if treated broadly, not mutually exclusive. On the contrary, if the data found to support either be clearly and firmly held, they might both be put to the highest possible uses. Many hema-

tite deposits in Spain occur in close association with the Trias in all sorts of positions, and with "igneous" rocks. Would it be worth while to compare them very carefully with Cumberland? Cynicism suggests that iron being such a ubiquitous element, and iron ore being indefinable through its many varieties, the tracing of such connections may be futile. If, however, a sufficient number of instances be considered and a sufficiently broad outlook be maintained, the universality of iron, the glory of its many colours, forms, reactions, and associations may provide just that illumination for which the world waits to-day on the subject of the continuity of development of rock species.

Let the data from Cumberland be collected and compared with similar data, from, say, Bilbao, Almeria, Lake Superior, India, and Brazil, and I am sure that we should be well on the way towards taking a more credible view of the "igneous" rocks than is at present current among the mass of men. The great work done by Van Hise and his collaborators at Lake Superior requires revision. The question of the "greenalite" could, I imagine, be illuminated by comparison with certain features of the Bilbao district.

The most striking suggestions, however, come from the tropics. In this letter I cannot enter upon this subject, but merely state my belief that, by way of iron ore, the new knowledge and new suggestions from the tropics could be brought into touch with the older order of thought which grew up in Europe, and the result would be to the delight of all concerned if they will have the faith to try it.

In the meantime in Cumberland let the infiltrationists be bold but not neglect Mr. Kendall's greenstones. It must already have been suggested that the source of the alkalies in the igneous rocks of the region may be sought in sodium and potash deposits of the Trias or at least in the seas which have swept over Cumberland from time to time. Yet such a hypothesis can hardly be discussed in terms derived from the "crust" view of the earth. If, however, we suppose that alkaline silicates can grow in a field now partially and imperfectly represented by the "stratified rocks," sometimes with high temperature and consequent complications, sometimes without, a comparative study of iron ore regions might help towards a different view.

Perhaps you, Sir, may allow me to return to the subject in a later issue.

J. H. Goodchild.

London, March 25.

Cementation Process and Vein-Filling.

The Editor:

Sir—The lecture on the cementation process delivered by Major Standish Ball at the Mining and Metallurgical Club last month was extremely interesting from several practical points of view. The building of an underground dam and the cementing of diamond-drill holes are within my own experience, but the cementing of drill-holes, in my case, was undertaken merely for the purpose of solidifying broken ground which was subsequently drilled. I have had no experience of filling underground fissures or cavities with cement in order to keep out water (though if such water carried "silt" of any kind the matter might require to be dealt with by lining or cementing), and until the above lecture I had not seen specimens of fissured rock which had been subjected to the cementation process.

A cursory examination of one of the specimens exhibited at the lecture suggests that considerable valuable information as to vein-filling might be obtained by an examination of many specimens mined from rock which has undergone the treatment. If those in charge of cementation work are made aware of the great interest which attaches to information on the circulation of cement and other liquids or semi-liquids in fissured rock, I am inclined to the belief that much valuable information would be collected by them, information too which might be of considerable economic value and might be a means of practically demonstrating matters about which hitherto we have only been able to speculate.

Further use for cementation, it occurs to me, is in connection with wells and bore-holes used for water supplies. Some thirty years ago I carried out a lot of tests in connection with the sinking of a large well with a deep bore-hole, and also made many tests of older wells which had become brackish by infiltration of sea-water. From the results then obtained, I believe that there should be considerable scope for increased use of the cementation process for the purpose of shutting out surface drainage, or underground feeders of exceptionally hard or brackish water from well waters intended either for domestic or technical purposes.

Stephen J. Lett.

London, March 17.

[Mr. Lett's suggestion that engineers should study the process of "vein-filling" in cementation is a good one, and they are encouraged to send the results of their investigations.—Editor.]

BOOK REVIEWS

Economic Mineralogy. By THOMAS CROOK. Cloth, octavo, 492 pages, illustrated. Price 25s. London and New York: Longmans, Green & Co.

The author states in the preface that the book is intended for those who wish to restrict their attention to the utilitarian side of the subject, and this aim is kept in view throughout the book. After a brief introductory chapter, the crystal forms of minerals are summarized in Chapter 2, it being stated that this is intended more as an introduction to crystal optics than as crystallography. The next chapter deals somewhat briefly with the physical characters of minerals, and includes clear descriptions of the construction and use of the Jolly balance and of the Westphal balance so far as the determination of the densities of liquids is concerned, but the use of the instrument for the determination of the densities of solids is not described, nor is the hydrometer mentioned.

Chapter 4 deals with the elements of crystal optics, and the author is to be congratulated on having dealt with a subject which gives some difficulty to the beginner in an extremely lucid manner. Then follows a chapter on the chemical examination of minerals, and one on the physical analysis of crushed rocks and alluvials which is thoroughly good. One notes, however, that the vanning shovel is not mentioned though the principle of vanning is suggested. The notes on heavy liquid, magnetic, and electrostatic separation are all that the student should require.

Chapter 7 deals with the geology of mineral deposits, and is necessarily brief and somewhat superficial. It includes a good classification of the deposits and a summary of the deposits in relation to the chief periods of igneous intrusion and orogenic movement.

The next three chapters deal with the descriptive mineralogy of the minerals arranged in groups as ore-minerals, gem-minerals, and miscellaneous economic minerals. The minerals are arranged according to the metals, which is justified by the list of occurrences and associations of the ores of each metal at the end of the description of its minerals. For instance, the description of the lead minerals is followed by four pages dealing with the chief occurrences of lead ores and their associated rocks and minerals.

A series of determinative tables concludes the volume. In the first the minerals with metallic or sub-metallic lustre are tabulated with their physical characters, while the minerals with non-metallic lustre have columns for refractive index and birefringence instead of colour and streak. This is a decidedly useful innovation. A table grouped according to specific gravity follows, and finally a table of some minerals grouped according to colour. It is doubtful if this last is of much assistance to the student, who is scarcely likely to call molybdenite black, or covellite either in many specimens.

The book is well printed and arranged, and the illustrations are good.

The present writer sympathizes with the author in his plea for the microscope as an aid to the quick identification of minerals, and would suggest that a description of the use of the eye-piece micrometer might be usefully added in a future edition.

The book can be strongly recommended to the mining engineer and the economic geologist.

E. H. DAVISON.

Manganese: Uses, Preparation, Mining Costs, and Production of Ferro Alloys. By C. M. WELD and Others. Bulletin published by the United States Bureau of Mines.

Before the war the world's output of manganese ore was furnished by the Caucasus, India, and Brazil. The Caucasian output ceased in 1914, and the demands of the European Allies were met from Indian sources, leaving the Brazilian supply for the United States. Although production in Brazil was largely increased during the war, the quantity sent to North America was insufficient, more especially as submarine activity reduced in quantity British supplies of ferro-manganese reaching the United States. A comprehensive survey of the domestic deposits was undertaken by the American Bureau of Mines, and their intensive development followed; while the Ferro Alloys Committee of the American Iron and Steel Institute endeavoured to modify the practice at steel works, so that lower-grade ferro alloys, made from American ores, could be used in place of the higher-grade material preferred and hitherto used. In the pre-war period, the output of manganese ore in the United States was negligible, but had the Armistice not intervened, it would have reached 300,000 tons of manganese ore containing not less than 35% manganese. This, together with the Brazilian and Central American supply, as well as the modifications in steel-works practice, enabled a stock of one year's consumption of ore to be accumulated in 1918.

With a view to assisting producers of manganese ores, the Bureau of Mines published

mimeographed bulletins dealing with the industry from time to time, and these reports are now published in a more permanent form as Bulletin 173.

This work is a valuable production, and reflects credit on all concerned in its preparation. While primarily prepared for American use it contains so much material not hitherto available, that it cannot fail to be of value to all interested in the utilization of manganese ore. It is evident that much information, which in normal times might be considered confidential, has been freely placed at the disposal of the compilers of this bulletin, although two firms are mentioned as having refused their co-operation in the investigation. The bulletin contains eleven chapters, each constituting a separate report on a definite subject by different observers, and consequently there is a certain amount of overlapping, which is recognized.

Chapter 1 deals with the uses of manganese, prices, and statistics. It is acknowledged that the Price Schedule of May 28, 1918, which refers to 95% of the manganese consumed in the United States in steel production, is mainly historical, for although following the Armistice prices remained high, the recent heavy fall in ocean freights has brought about a 66% reduction in the figures given. It is probable also that the penalties for silica, phosphorus, etc., relaxed during the war period, will be re-imposed as supplies become more plentiful.

Chapter 2 discusses the uses of manganese other than in steel making, which are responsible for increasing consumption. The detailed information regarding the physical and chemical requirements of the manganese dioxide ore for dry cells, glass making, and for paints is most useful. The penalty for iron, not imposed during hostilities owing to the cessation of supplies from the Caucasus, will probably not be re-introduced, as only copper, nickel, and cobalt minerals are now considered prejudicial in ore used for dry cells. Mention is made that manganese ore is no longer used for making chlorine gas, as the latter is an abundant product in the manufacture of caustic soda and potash.

The use of manganese ore in the manufacture of manganese bronze which replaces steel effectively, when subject to the corrosive influence of sea water, is also dealt with, and it is pointed out that only 0·05% of manganese is usual in the high-grade alloy, its function being as a carrier for the iron necessary to ensure the required strength and elastic limit.

Chapter 3 deals with the problems involved in the concentration and utilization of domestic low-grade manganese ore. The American mineral is mostly the result of secondary concentration, and often occurs as shallow deposits of nodules, or irregular masses disseminated in clays. The effect of associated impurities is discussed, and reference is made to calcination of the carbonate, which, however, would only be effective with low silica contents, owing to the tendency to form silicate of manganese.

A list of concentration processes is given, and cost data which show the beneficial effect of treating mineral which would otherwise be unsuitable for ferro-alloy manufacture. The figures refer to cherty California ores low in iron, and would require serious modification for other types of mineral. The plant used is not described, but the ratio of concentration is 2 or 3 to 1, and the war-time cost appears low, at 75 cents per ton of finished product.

Mention is made that the separation of silica, when chemically combined, cannot be carried out by wet or gravity processes, and this fact prevents the utilization of large deposits of manganese silicate ores in the United States, and also the successful beneficiation of the waste material at some Brazilian and Indian mines.

Chapter 4 deals with the preparation of manganese ore. The picking and screening of manganese ore without the assistance of water, referred to as dry mining, is mentioned as a temporary expedient before the erection of a washing plant, but to be effectual it requires a minimum of 10% of ore, and even this would be insufficient in normal times. It is asserted that log washers have treated successfully very lean material, but a ratio of ore to gangue of 10% is considered a fair average. Associated iron having a similar specific gravity requires to be hand-picked. Flow-sheets of several concentration plants are given for mineral associated with clay, followed by a description of a standard arrangement consisting of grizzlies 2 to 4 inches between bars, log washers, revolving screens, picking belts, jigs, and shaking tables. Dry concentration is referred to as applicable where water is scarce, and a plant is described which, however, had not been operated on a commercial scale when the report was written. It consisted of a revolving drum where the material would be dried before passing on to a revolving screen, from which the coarse material would discharge on to a picking belt, the smaller sizes of material being dealt with in jigs.

It may be noted here that the installation of washing plants, some years ago, enabled the large waste heaps, accumulated around the Caucasian deposits since the mines were first

operated, to be successfully beneficiated at a low cost. Washing plants were also operated prior to 1914 on the detrital ore of the famous Morro da Mina deposit in Brazil, and in the Bukowina.

Chapters 5 and 6 deal with the leaching of manganese ore by sulphur dioxide, and the Jones direct-reduction process for the production of a silico-manganese alloy. Both these processes were only investigated as a war measure, but it is suggested that the leaching process might be applicable to mineral containing copper, lead, or zinc; while the Jones system might be used in the preparation of a manganese alloy from ores in which iron is so intimately associated that ordinary methods of gravity or magnetic separation are impracticable. If the Jones process could be made economically sound, it would have a wide field of usefulness, for manganiferous iron ores are widely distributed. The process is in two stages; in the first, iron and slag containing most of the manganese is produced; and in the second stage this latter is smelted to produce a manganese alloy.

Chapter 7, on the cost of producing ferro-grade manganese ores, deals with a difficult matter, inasmuch as the principal factors have varied so greatly during the war and since. The manganese ore output of the United States during the war consisted of 20% carbonate ores and 80% oxide mineral. The former was got by mining underground and required no concentration, but the latter was associated with clay, chert, etc., and required treatment. Many of these deposits are erratic and others give place to silicates in depth.

Much of the domestic mineral was hand-cleaned, but where it was mined and sent for treatment, the average cost was $7·50 and treatment $6·50, or say $14·00 in all. The milling costs differ widely from those already referred to, and the presumption is that the ratio of concentration and quantity handled varies in the two cases. The total cost at furnace of the domestic mineral during the war is put at $0·65 per unit of 40% ore, although it is calculated that this could be reduced about 15% in normal times. Of the foreign ores only those of Cuba and Brazil are considered; the first is of similar grade to the domestic mineral, but the second normally contains 50% manganese.

The Brazilian costs are in dollars, but in view of economic changes, it would have been preferable also to give the native currency costs and rate of exchange at the time of making the estimate. The average costs into ship of Brazilian ore at Rio is put at $15·00 in 1918, and this together with $15·00 ocean freight is equal to 67 cents per unit for 45% ore, at American ports. The authors endeavour to estimate future prices and suggest that if ocean freight falls to pre-war figures, it would be possible to place Brazilian ore in the United States at 40 cents per unit. These conditions have been reached, for the Brazilian exchange has fallen to 10d. and ocean freights to a little over a third of those of 1918. It is therefore doubtful if, under normal conditions, American ores can be produced in competition with foreign supplies, unless assisted by a high protective tariff, which is at present under discussion by the Government. The work of the Bureau of Mines has shown, however, that a good supply of manganese ore can be produced in the United States, and if some economically successful method could be evolved for beneficiating the manganese silicate ores, it is probable that the country might, in time of national stress, be self-supporting.

Chapter 8 deals with the production of manganese alloys in the blast-furnace. Particulars are given of the operation of a number of furnaces producing ferro-manganese and spiegeleisen, the observations extending over 10-day periods. The working of a blast-furnace making ferro is more regular than when producing pig iron, but the problem of getting the manganese into the alloy, instead of into the slag, is not easy. In order to account for the greater amount of fuel required, it is pointed out that the manganese is reduced from its oxide by solid carbon near the tuyeres, and, as the CO_2 resulting is again reduced by solid carbon, there is a loss of heat. The balance of heat units is used in heating ascending gases, which are three times greater than in pig iron furnaces per lb. of ferro produced.

An elaborate analysis of the operation of the furnaces is made, and both the slag and stack losses are found to vary within wide limits and average 14·7 and 12·8%. An investigation was made into the effect on these losses of (*a*) quantity of fuel, (*b*) basicity of slag, and (*c*) rates of driving, and it was found that the percentage of manganese in the slag was reduced by raising blast temperature, increasing basicity of slag, and charging more coke; while it was increased by fast driving and carrying a greater slag volume. The volatilization or stack loss did not appear to have any relation to these factors.

The authors state that by making five changes in practice, the eleven furnaces considered could have raised their recovery to 79%, and using the same ore, could have increased their

tonnage 59% and also increased their profit appreciably. The changes suggested are: Using a better quality of coke, using a better grade of limestone, using less fuel, running with a more basic slag, and driving faster.

In dealing with the manufacture of spiegeleisen, it is pointed out that to obtain manganese, the smelting of manganiferous iron ore takes 78% more carbon than when making ferro-manganese, although this may in part be due to the high ratio of silica to manganese in these ores, as compared with manganese ores proper. While efforts were made to increase spiegeleisen consumption during the war, owing to it being possible to manufacture this alloy from domestic ores, it is probable that the tendency to utilize only high-grade ferro alloys will now reassert itself, especially for the manufacture of mild steel, as spiegeleisen introduces too much carbon. The average recovery of manganese in making spiegeleisen is only 60%, as compared with 70 to 75% when making ferro-manganese. It is interesting to note that 1/6th of the loss goes to the stack and 5/6ths to the slag in spiegeleisen manufacture, while the losses are equally divided in making 80% ferro-manganese.

Chapter 9 deals with the national importance of allocating low-ash coke to manganese alloy furnaces, and points out that silica in fuel employed in making ferroalloys produces a greater loss than when smelting pig iron, as in reducing manganese ores the slag loss is in proportion to its volume. The review of the situation makes it clear that if the purer coke were allocated to furnaces manufacturing ferro alloys a great saving of manganese would be effected.

Chapter 10 discusses the electric smelting of domestic manganese ores. In order to determine experimentally if the low-grade domestic silicious, phosphoric, and ferruginous manganese ores, not amenable to ordinary methods of gravity concentration, could be used for ferro-alloy manufacture, a number of charges were worked in a small 65 kw. furnace.

In dealing with mineral containing more than 25% silica, it was found that an acid slag contained less manganese than a basic one. Dephosphorization was carried out as in the Jones process by concentrating most of the phosphorus in an alloy, and the manganese in slag, which was subsequently reduced with the production of a ferro alloy reasonably low in phosphorus, and with a 60% manganese recovery. Experiments on the ferruginous Cuyana ores by this process are also said to have been satisfactory. These results are not, however, of immediate interest, as only very exceptional circumstances would justify the electric smelting of such low-grade ores.

A number of electric furnaces producing ferro-manganese were operated in the United States during the war on a commercial scale, and others were in construction when the fall in prices, following the Armistice, brought about a suspension of operations. Particulars are given of the furnaces operated which, using the domestic manganese ores containing 15 to 25% of silica, produced an 85% ferro-manganese, with a recovery of 70 to 80%, which compares favourably with that of the blast-furnace. The power consumption was 5,000 kw. hours, and the coke used ranged from 1,400 to 1,200 lb. per ton of alloy in a 3,000 kw. furnace.

There is some difference of opinion regarding the most useful size of furnace. One operator maintains that a furnace with 1,150 kw. capacity has a recovery of 90% when producing six tons per day of 80% ferro-manganese; while for a 2,250 kw. furnace the recovery is only 70% with a production of 8 to 10 tons of alloy per day. It is found that the manganese stack-loss in the electric furnace is lower, and the slag loss about the same as when reducing manganese ore in the blast-furnace.

Figures are given, based on commercial practice and experimental work, of the estimated cost of producing 80% alloy in the electric furnace. Using domestic mineral containing 40 to 42% manganese and 13 to 20% silica, there should be a recovery of 72 to 75% of manganese with a 12% loss in the slag. In a 3,000 kw. furnace the power consumption would be 5,000 to 5,500 kw. hours; 153 lb. of electrodes and 1,800 to 1,900 lb. of coke would be used, with a production of 10 to 11·7 tons of 80% alloy per day. Better results would no doubt be obtained with mineral of higher grade from foreign sources.

The conclusion arrived at is that, while in normal times it would not be profitable to smelt manganese ore electrically in the United States, it might be done during a period of industrial activity or national stress. If it were possible to obtain water power at a very low rate, say 0·25d. per unit, in the vicinity of some of the foreign high-grade deposits, it is probable that electric smelting would be successful, and it is interesting to note that the Brazilian Government has recently decided to reduce the export taxes on manganese ore to any operator who undertakes to smelt electrically in Brazil 10% of his output of ore.

Chapter 11 is the report on the use of manganese alloy in open-hearth steel practice, and it is pointed out that manganese is not an ex-

pedient, but a basic requirement of successful practice in making steel. The principal function of manganese is to reduce ferrous oxide in the bath, and for this 0·35% manganese might be required. Manganese also eliminates sulphur and improves the rolling properties of the steel, as well as retards coalescence of grain growth, which would require 0·35%. It is also necessary to produce certain physical and mechanical properties of steel, so that the total consumption may be put at about 1 to 1¼% per ton of steel produced. Other deoxidizers, as silicon and aluminium, have a tendency to cause inclusions in steel, and they also encourage grain growth and leave the metal in poor condition for rolling and forging.

In order to reduce the consumption of manganese, the following recommendations to steel manufacturers were made: (*a*) Use of molten spiegel mixture; (*b*) high residual manganese in the bath; (*c*) use of silico-manganese alloy in place of the 80% material. All of these expedients are in use both in Europe and the States, in a limited degree. It is pointed out that the first cannot become general owing to the introduction of too much carbon for mild steel. The high residual manganese in the bath does not reduce consumption, except as it enables low-grade manganese ores to be used in making the pig iron. The use of manganese-silicon alloys is governed by the amount of silicon that can be tolerated in the steel, as it is prejudicial in material which must be welded, as well as for sheets and plates. In acid steel practice figures are given which show the consumption of manganese and silicon to be smaller, when introduced as silico-manganese, than when used as ferro-manganese and ferro-silicon; while for basic open-hearth practice results obtained suggest that the use of silico-manganese protects manganese in "oxidized" heats. It is probable that the use of this alloy will become more general.

In conclusion it may be stated that while the extreme shortage, and high price, of manganese ore during the war was a powerful incentive in the search for new supplies of high-grade ore, none appears to have been found, as the West African and Sinai deposits, now regular producers, were pre-war discoveries.

Further, efforts were made during the war, more especially by steel manufacturers of the Central Powers, to find some equally efficient substitute for manganese, without success. It is evident, therefore, that the future of the already known deposits, and the manufacture of ferro-manganese, are assured. American makers of ferro alloys are endeavouring to obtain tariff protection against the British product, and if successful, it is probable that future exports of ferro-manganese from this country to the United States will be smaller than in the pre-war period.

HERBERT K. SCOTT.

NEWS LETTERS.

TORONTO.

March 10.

MINERAL PRODUCTION OF CANADA.—The preliminary report on the mineral production of Canada during the calendar year 1920, issued by the Department of Mines, gives the total value as $217,775,080, which establishes a new high record. Compared with the production in 1919, valued at $176,686,390, an increase of 23·3% is shown. The metallic output was valued at $77,236,370, the quantities and values of the principal items being as follow: Gold, 766,912 oz., $15,853,478; silver, 12,793,541 oz., $12,908,683; copper, 81,155,360 lb., $14,166,479; nickel, 61,136,493 lb., $24,454,597; lead, 33,985,974 lb., $3,038,346; zinc, 40,166,200 lb., $3,081,149; cobalt, 593,920 lb., $1,484,800; and pig iron from Canadian ore, 75,869 tons, $2,066,997. There was a noteworthy increase in the production of coal, which amounted to 16,623,598 tons valued at $77,326,853, being 21·5% in quantity and 42% in value in excess of the output of 1919.

PORCUPINE.—There has been a further curtailment in the allotment of electric power to the producing companies. The Hollinger Consolidated is now only getting 1,500 kilowatts, as compared with its full requirements of approximately 10,000. By the use of its steam auxiliary equipment it is able to continue work at about one-third capacity, treating about 1,300 tons of ore per day at an extra cost of about $900 daily. The company has entered an action for damages against the Northern Canada Power Co., Ltd., on account of losses sustained by reason of power shortage, the outcome of which will be of much interest to mining operators whose business has suffered from the same cause. The annual statement of the Hollinger Consolidated for 1920 indicates that, despite all drawbacks, the company has had a prosperous year. Its total revenue was $7,162,611, as compared with $7,063,099 in 1919, and the net profit was $2,675,274, as against $2,321,290. The sum of $461,274 was added to the surplus, bringing the total up to $6,462,918. The net yield of ore treated per ton was $9·56, as compared with $9·40, and the value of the ore reserves

was estimated at $36,596,059, as compared with $39,928,430. During 1920 the Dome Mines treated 295,220 tons of ore, the yield from which amounted to $2,005,640, an average extraction of $6·80 per ton. In addition the company received about $200,000 exchange premium, which would bring the average yield up to about $7·50 per ton. The McIntyre has been encouraged by the development of a large ore-body, believed to come in from the Hollinger, on the 1,000 ft. level, to plan an increase in its milling equipment, augmenting its present capacity of 600 tons to about 900 tons, which, according to an estimate based on last year's figures, would give an annual production of $3,000,000. The additional crushing and grinding machinery has been ordered and will be installed as early as possible. The McIntyre has secured power rights at Sturgeon Falls on the Mattagami River, 30 miles from the mine, capable of generating 9,000 h.p. Unless the power company can increase the supply of electric energy sufficiently to prevent a repetition of the shortage now experienced, the McIntyre will generate its own supply. The coming season promises to be a very active one. Labour is plentiful and efficient, and as soon as the spring has fairly set in work will be resumed on many prospects and new enterprises will be undertaken.

KIRKLAND LAKE.—The annual statement of the Lake Shore for the year ended November 30, 1920, showed an income of $528,028, the net amount carried forward after all deductions being $104,992. During January the production was valued at $37,375 from the treatment of 1,674 tons of ore, the extraction averaging $22·34 per ton, the mill running 82% of the possible time. A station has been cut at the 600 ft. level, at which lateral work is in progress. At the Wright-Hargreaves the new mill of 180 tons capacity is ready for operation, but it will not be started until May 1, by which date a full supply of power is assured. A 4 ft. vein of high-grade ore has been encountered on the 700 ft. level of the Kirkland Lake mine.

COBALT. — The silver-mining industry is much depressed owing to the low price of silver, coupled with power shortage, and it is somewhat doubtful whether many of the mines which closed down over the winter will be reopened until market conditions show improvement. The Mining Corporation of Canada has closed down its mines and mills indefinitely, and will make extensive alterations in its concentrating and cyanide plants so as to be in a position to handle an increased tonnage at lower cost when work is resumed. The company is the second largest silver-producer in Canada, its output last year being 1,806,274 oz. of silver. The Moore Filter Co., of New York, has brought an action against the Nipissing Mining Co., claiming $600,000 damages for the infringement of their patent rights in the filter used for the filtration of metal-bearing slimes. The Oxford Cobalt will shortly resume operations. The shaft will be put down from 180 to 350 ft., at which level a cross-cut will be run to tap the vein. The Chambers-Ferland has opened up at the 410 ft. level a rich vein 2 in. wide coming in from the Nipissing, which in some places yields ore carrying 5,000 oz. to the ton.

SUDBURY.—The mine and smelters of the British American Nickel Corporation have been closed down owing to unfavourable market conditions, throwing 600 or 800 men out of employment. Only a small nucleus of the force has been retained, so that when a change for the better occurs production can be resumed at short notice. The refinery of the company at Deschenes, Quebec, employing 400 men, will also close shortly. The company was a war enterprise, started in 1916, in which the British Government was heavily interested. The Mond Nickel Co. has reduced the wages of their employees 40 cents per day.

VANCOUVER, B.C.

March 1.

SHEEP CREEK.—With the gradual decrease in the cost of labour and supplies, and with the general slump in base-metal mining in this Province, mining men seem to be turning their attention, once again, toward gold-mining. An important deal that has taken place within the last few weeks is the bonding of the Queen mine, at Sheep Creek, near Nelson, to C. H. Cassill, of Spokane. The people of Spokane, it may be said in passing, take a far more active interest in and derive a greater benefit from the mining industry of British Columbia than the people of any city in the Province. Some of the biggest and best paying mining enterprises in the Province were started in Spokane. The Queen mine was located towards the close of last century, and mining operations were carried on busily until 1915, when a cave in the main winze caused the closing of the mine. Up to this point the mine had produced more than one and a half million dollars in gold. The mine remained closed until the end of the war. In 1919 it was bonded to A. W. McCune, the well-known Butte operator, and a long tunnel was driven. The result of the work, however, was inconclusive; gold-mining generally was very

much in the doldrums at the time, so the work was abandoned. In the meantime, C. H. Cassill had bonded the Ore Hill group, which adjoins the Queen, and on it had developed a strong vein over a distance of more than 2,000 ft. This vein has all the characteristics of the Queen vein, and the trend of the strike is in a direction that led Mr. Cassill to suppose it was the same vein. He, therefore, obtained a short option on the Queen, had it examined by J. C. Haas, of Spokane, and the present bond and lease, which will expire on July 1, 1923, has resulted. On the bottom, or 700 ft. level, the vein is exposed over a distance of 800 ft., is from 8 to 33 ft. wide, and is said to have an average value of $9 per ton in gold. There is a 20-stamp mill on the property, and ample water rights on Sheep and Wolf creeks go with it. The flume and the mill, after a period of six years' idleness, will necessarily need considerable repair. Mr. Cassill proposes to combine the two properties, the Queen and the Ore Hill, and float a company to be known as the Queen-Ore Hill Mines, Ltd., with a capital of $250,000, which is the actual price he is paying for the two properties.

GRANBY CONSOLIDATED.—The Granby Consolidated Mining Smelting & Power Company got all the best of its two appeals against the Esquimalt and Nanaimo Railway for title to the Cassidy Colliery coal areas, on Vancouver Island. The Granby was given full title to the Dunlop property, and the Court found that title to the Ganner property was vested in the Granby Company, but in case of assessment for damages in respect to the coal-rights these were to be considered as "coal in nature." The outside price at this rate is stated to be $150 per acre for the 200 acres involved, so the utmost that the Granby can be called upon to pay is $30,000. When it is remembered that the Granby has expended more than $2,600,000 in the purchase of the property, purchase of timber rights in connection with it, and in the equipment of the colliery and building of the town, to which must be added another $2,000,000 for the building of the by-product coke ovens, at Anyox, to carbonize the coal, the present liability is comparatively small. The counsel for the E. & N. Ry. gave notice of appeal to the Privy Council, and, pending the result of this appeal, the Granby has been given the right to continue mining coal from the property. E. E. Campbell, assistant manager, and for many years in the employ of the Granby, has retired to become general superintendent for the United Verde Extension Mining Co., at Jerome, Arizona, and J. A. Bancroft, professor of geology at McGill University, has been appointed in his place. Prof. Bancroft will take up his new duties at the close of the present university term. Granby is doing some excellent work; it is producing more copper and at a cheaper rate than at any time since the armistice; in fact, it is claimed that, but for the interest on its bonded indebtedness, Granby would be producing more cheaply than any concern on the continent. With the exception of an insignificant amount from the Rossland mines, and a small amount from the Belmont-Surf Inlet mine, Granby is the only concern producing copper in the Province.

MISCELLANEOUS MINING NEWS.—The Consolidated Mining & Smelting Company is maintaining an excellent production from its own mines, principally the Sullivan. The first six weeks' ore receipts at the Trail smelter amounted to nearly 50,000 tons, which is about 8,000 tons more than the quantity received over the same period of last year. With the exception of a little more than 1,000 tons, this has all come from the company's own mines. Owing to the fact that the company during the slump in the prices of lead and zinc is paying only in warehouse receipts, few concerns are financially able to ship ore to Trail. In fact, the mines in those districts that have been relying on the Consolidated company to treat their ores are nearly all closed. The Florence Silver Mining Co. is proposing to put a steamer and barges on Kootenay lake, thus enabling it to ship concentrate to Five Points, and thence by the Great Northern to either Northport or Kellogg, in the United States. This would render it independent of the Canadian Pacific Railway, for which company few of the mine-owners have a good word to say. It is likely that the Bluebell Mining Co. will follow the same course. The Slocan and Slocan City mines are not so fortunately situated geographically.

The Belmont-Surf Inlet Mines, Ltd., a subsidiary of the Tonopah-Belmont Development Co., continues to give a good account of itself. The net earnings for the quarter ended September 30 was $68,640, and was the principal source of income to the parent company. The gold, which is the principal product, is collected with the silver and copper in the form of a concentrate that is shipped to the Tacoma smelter.

Since the closing of the Nickel Plate mine, at Hedley, last fall, T. Griffin has been exploring his property near the Nickel Plate, and has developed a lode some 100 ft. in width, the whole of which is said to be shipping ore. A trial shipment is being prepared, but, owing to the position of the property, high up on the

mountain side, considerable trail building will be necessary before ore can be taken from the property.

The discovery of a deposit containing strontianite and celestite is reported from Princeton, and at the present time is being explored with a view to recovery of the minerals on a commercial scale.

OIL.—The Imperial Oil Company has shipped an extra heavy drilling outfit, capable of boring 4,000 ft., to Pounce Coupe, which is situated in the Peace River Block, a national forest reserve, the oil-rights of which are vested in the Dominion Government, although it is situated within the boundary of British Columbia. Oil seepages have been noted along the banks of the Pounce Coupe river, a tributary of the Peace river.

C. M. Rolston, local manager for the Imperial Oil Company, has announced that arrangements have been made with California producers for the delivery of 600,000 barrels of oil during the present year; consequently, it is likely that the company's refinery, at Ioco, near Vancouver, which was closed last fall, owing to inability to get crude oil, will be re-opened shortly. It was expected that the refinery would be closed until June, when arrangements had been made for a supply of crude oil from Mexico.

KALGOORLIE, W.A.

February 21.

MINING CONDITIONS IN WEST AUSTRALIA.—In many country cemeteries one sees recorded on a tombstone a verse which relates that the deceased was troubled sorely with affliction for a very long time, in spite of the efforts of his physicians. For over thirty years the mining industry in this State has suffered many afflictions, of which the greatest has been the promotion of wild-cat companies, due to the inherent desire of mankind for a gamble. Unfortunately too often "the cards have been stacked," so that people in all good faith put money into companies, accepting the opinion of men who had not the training nor experience necessary to size up the possibilities (if any) of the property on which they were paid to report. The trail of the feline, which started at the Coolgardie boom, followed at intervals at Kalgoorlie, Bullfinch, and quite recently at Hampton Plains and Mt. Monger, has drawn attention to the worst aspect of mining and detracted from the good work done on the producing mines.

The most recent affliction and one that threatens to kill the industry is the award of the Arbitration Court given at Kalgoorlie. The miners themselves never expected to receive a minimum wage of 16s. per day. The other penalties on the industry, including the fortnight's holiday each year on full pay and overtime rates, amount to so much that the border-line between profit and loss has now been crossed by several of the mines on their previous ore-reserve average. The result is that the grade has to be increased, where possible, which means the earlier demise of the mine, or where it is not possible to do this operations must cease.

A statement frequently made by trades unionists, even by Presidents of Arbitration Courts throughout Australia, is that if an industry or a mine cannot afford to pay a living wage (a term which is too variable to define) it is better for that industry or mine to shut down. That at first sight seems sound, but the point is that the employers realize the economy of paying a good man a high rate of wage, if he will produce a profit on that wage by work done, and the more men he employs on contract who can and do earn above the current wage, the cheaper are his costs, up to a limit. However, what he does object to is the payment of men who will not, or cannot, produce the value of the minimum rate of wages which they demand, and by the award of the Arbitration Court must now be paid. In a small mine, men can be picked and those who will not do their bit are weeded out, but when it comes to employing a large number there is an increased proportion of those whose work results in a dead loss to the employer. During the war the pick of the mine employees enlisted; the older miners could not maintain the average, while those who did not enlist were, as a general rule, the least willing workers. This has meant a general decrease in efficiency per man and consequent increase in the cost per ton. Since the Lancefield and Sons of Gwalia have ceased operations (to which reference will be made later on) a great many good men from these fields have moved into Kalgoorlie to look for work. The managers there can now replace the red raggers who will not work for these men who are anxious to make good money on contract. For some years past, on some of the big mines, the supply of ore in the bins on Saturday night has been hardly sufficient to keep the mills going until Monday morning. The advent of a more plentiful supply of men from the above mines has relieved the position considerably in this respect. Thus the mines which can survive the transition period will no doubt last for some time longer, at the sacrifice

of others whose reserves are too low in grade to pay the high wages, together with post-war prices for stores and machinery spares.

LANCEFIELD. The Lancefield mine, which has been ably handled by a small company, whose shareholders are themselves mining engineers, has had to shut down, because the margin of profit has been cut out by the award. Before doing so, Mr. Ridgeway, managing director, called a meeting of the employees, and made them an exceptionally generous offer to take over the mine and mill, on a nominal tribute of 1s. per ton crushed, on condition that the manager was nominated by the company. The latter offered to finance the scheme until returns were available. On the advice of the Labour Union representatives, the offer was turned down, almost without discussion. This is an answer to the labour leaders who in times of stress suggest taking over the mines, to show how they could be run by miners. They evidently realize that the mine-owners' profits are not so great as they would believe, or are frightened to take the risk which they expect the company to do of making it pay. There is no question as to the amount of ore available, so it is not a matter of having to develop it before they can mine it.

SONS OF GWALIA.—The Sons of Gwalia, after a career of many years as the biggest gold producer outside of Kalgoorlie, has had the misfortune to have its power and crushing plants destroyed by fire. It is now a question for the directors to decide upon the size of a new plant which is warranted, and also how long it will be before it can be erected. Meantime hundreds of men are out of work, and the whole town of Leonora is indirectly affected. The Minister for Mines is endeavouring to arrange some scheme whereby a number of these men can reopen abandoned mines in the district, possibly with the active help of the Gwalia Company, and crush the ore at the State Battery under a board of supervisors. It is an experiment which will be watched with interest, and its success will depend upon the amount of co-operative effort put into it by the workers, rather than on any artificial spoon-feeding by the Government.

STATE AID FOR PROSPECTORS.—The Minister for Mines has made a proposal to subsidize prospectors to the extent of 70s. per week per man, but as it has been pointed out by those who have taken an interest in this work, all the easily found lodes and deposits in West Australia have been discovered, and if any subsidized prospecting is to be a success, it must be under the supervision of a mining geologist. It is not only a question of systematized information, which the geologist has to blend with the practical knowledge of the prospector. It is the economic reason that, if the State pays the prospector wages, it must see that his work is carried out to the best advantage.

HAMPTON PLAINS.—At Hampton Plains work is now mainly confined to the development of those mines on which payable ore has been found. On the Celebration, after some delay in the supply and erection of the winding and compressing plants, the main shaft is now 210 ft. down in very hard country. The sponsors of this property are still sanguine that, while the lode was poor at the 193 ft. level, the value of the ore will improve when it is cut in settled country. It will not be long before the shaft reaches a depth of 300 ft., when the question will be settled.

On Lease 81, which is on ground reserved by the Hampton Properties Company, the Celebration lode has been found carrying good prospects, and a shaft is being sunk to test it at depth. The same company is sinking two shafts on a lode on Block 45, which lies several miles to the east of the Celebration. At a depth of 50 ft. the lode in one shaft averages 1 oz. per ton over 6 ft., and in another 75 ft. along the line of lode averages 15 dwt. per ton over 8 ft. in width. Although this belt of country is typical of the Golden Ridge series of lodes, it appeals more to a mining man than the more porphyritic country on Block 50. The Boulder No. 1 Company had an option on an adjoining lease, but the lode they prospected, and considered not good enough, was on a different line from that described above. On Block 48, the Golden Hope winding and pumping plant is now being erected, and as the railway line has reached this property, the company expects that it will shortly be able to send in regular consignments of ore to Kalgoorlie to be treated.

On the White Hope mine, the lode consists of hard sulphide ore, and the development work, which is necessarily slow, has so far not revealed any long shoots.

The Hampton Areas Company is having a geological survey of its blocks made by its resident manager, and as a result of his work it is quite possible that some new lodes may be found to be worth development. By referring to the map published in the MAGAZINE in October, 1919, it will be seen that the Hampton Properties and Areas companies hold blocks of land spread over a width of 30 miles, in which there is a lot of greenstone country, which has not yet been systematically prospected.

MOUNT MONGER.—Out of the dozens of companies floated and hundreds of mining leases taken up at Mount Monger during the recent boom, there have only been a few small crushings of rich patches of ore. One from the Prospector's (McCahon's) Mine of 38 tons was treated at Kalgoorlie last week for a return of 886 oz. of gold, and the tailing is expected to add another 200 oz., which will mean an average return of about £150 per ton. This ore was picked from a dump of 200 tons the balance of which is estimated to be worth 1 oz. to the ton.

The Monger Proprietary is the next mine to this, and has the surface portion of this pipe of rich ore now being developed. The Lass O'Gowrie lease, which was the cause of the rush to the field, and on which an option was taken at a very big price, has been dropped by the option-holders, and the company has gone into liquidation. With a well-known mining engineer, I made an inspection of this field a year ago, and while the prospector (McCahon) invited us to sample and see his workings, the owner of the Lass O'Gowrie refused us permission to make even a cursory inspection of his show. It has been my experience, in this State at any rate, that if a prospector has anything good he is willing to let a mining engineer inspect it; on the other hand, a refusal makes one doubtful of the value of the find.

RAVENSTHORPE.—At Ravensthorpe, mining is also at a low ebb. Not that there are no mines worth operating, but no improvement can be expected until some better means are devised for concentrating the lower-grade copper ore, so that the Government smelting works will not have to rely on high-grade ore alone, as at present. The supplies of the latter are not sufficient to keep the furnace going. Consequently the costs are higher than the industry can stand, with the present low price of copper. It is possible that if the Government were to put up a mechanical concentrator for the roughs, and a flotation unit to treat the finer sulphides, to be run in connection with the smelter, the whole of the ore, which is at present picked, could be mined and treated at a profit.

OIL.—During the stay of the Agent General in the State, several speculators, who believe that oil may be found near the south coast of West Australia, have met and given him their views on the matter, so that when he returns to England, almost immediately, he will be able to discuss the question with some firms who are anxious to prospect for oil. The Government Geologist, on the other hand, does not class any of that country as likely to be oil-bearing.

MELBOURNE.

February 1.

HYDRO-ELECTRIC POWER IN TASMANIA.—The sixth annual report of the Tasmanian Government Hydro-Electric Department gives a large amount of interesting information relating to the progress of the work undertaken by this public enterprise. An active policy of development is being carried out, although operations have been severely retarded owing to the conditions created by the war, and by industrial unrest. The shortage of cement in particular has seriously delayed the progress of the work of constructing the Great Lake dam, while the date of erecting pipe-lines and other equipment will be fixed by the time when cement supplies become available. Five new turbines and alternators, together with switch-gear and apparatus, are on order, but the work of completing the power station is being done in stages owing to the shortage of labour and cement. The excavations for the whole extensions are well in hand, and concreting has been commenced on that portion of the extension required to accommodate one unit.

The position of a new transmission line, running south, has been fixed, and most of the necessary towers have been ordered. This line will continue on the eastern side of the River Derwent to Risdon, instead of crossing at Bridgewater, as it was not found practicable to effect another crossing at this point. It is probable that as soon as the new transmission line is in service the existing line between Bridgewater and Hobart substations will be dismantled and re-erected along the same route on the eastern shore of the Derwent, thus considerably reducing maintenance costs. The completed transmission line will include four district circuits, one of which may be shut down from time to time for inspection and repair. The Launceston transmission line has been located, and a good start has been made towards clearing the route. The surveys did not disclose as good conditions from a wood-pole point of view as were hoped for, and the increasing cost of labour and insulators made it desirable to carefully investigate the question of whether a steel tower line would not, in the end, be more economical. Tenders have been called for the construction of towers, and when offers are received a decision will be arrived at as to whether wood or steel is most suitable material for the construction. It is

anticipated that the Launceston service can be given in about 18 months' time.

The necessary machinery for the Risdon substation is on order. At this substation the whole of the high-tension apparatus will be out of doors, only the low-tension switching, measuring, and repairing apparatus being under cover. The necessity for the Risdon substation being established to supply the Electrolytic Zinc Co., has made it desirable, in the interests of economy of operation, to make this the substation to supply Hobart, instead of the substation at present at New Town. This will be arranged for by taking up the supply of the first block of power to the Zinc Co. at Risdon, as soon as it is completed, then removing the outdoor portion of the present Hobart substation to Risdon, and taking up the Hobart supply with that; leaving the present indoor portion of the Hobart substation available for other use. It is intended to dismantle and re-erect this portion at Launceston in time to take up the supply of power to that city when required. Arrangements have been made to carry a high-tension line from Risdon substation to the present Hobart substation site to connect on to the Electrona transmission line extension, and this new interconnector will be used in the first instance to feed the Risdon substation. The machinery required for duplicating the Electrona substation has arrived, and will be erected at an early date. This will bring the capacity of this substation up to 8,000 k.v.a. Great difficulties were encountered in finding a suitable site for the new Arthur's Lakes dam. Tests pits that were sunk revealed porous country, but a suitable site has now been found, and tenders are being called for the construction of an earth-filled dam, which it is hoped can be completed during the coming summer. The steadily increasing cost of labour, without a corresponding improvement in the output per man on hand-work, is still a source of considerable anxiety. The basic wage at the Great Lake, at Liawenee, is 14s. per day, and 13s. 4d. per day at Waddamana, as compared with the average basic wage of 8s. 6d. per day when the work was first started. The high rate of exchange with America and the Customs duties on imported plant are also influences that have a severe effect on increasing construction costs.

The officers of the department are engaged in water-power surveys in various parts of Southern Tasmania, and the report shows what has been done on the Shannon, Little Pine, Ouse, Derwent, Styx, and Huon rivers and the Rolliston scheme. Surveys have been completed for the proposed scheme of the Huon river, and plans and estimates are being prepared. The proposed works include a dam 150 ft. high, flooding about nine square miles of land surface, and the power available will be about 20,000 b.h.p. The larger tributaries of the Huon are now being investigated. The surveys of the Rolliston scheme have also been completed, and this entails linking up several small catchments by means of races and a tunnel giving a total catchment of about 27 square miles. Four storage reservoirs will be provided by constructing dams across the Anthony river, Newton Falls, and Julia Creeks. The pipe-lines will consist of a 6 ft. diameter wood pipe, 12,000 ft. long, feeding two 48 in. steel pipes. The head available is 1,130 static, which gives about 22,000 b.h.p. catchment available at turbine shaft. The Styx river has long been regarded as the source from which Hobart's water supply must in the near future be augmented, but a further investigation has proved conclusively by exploration that no storage approaching suitable size exists here, and therefore any scheme must be based on minimum flow and auxiliary plant. The minimum flow is about 25 cu. ft. per second. A fall of about 500 ft. can be obtained by a diversion of the river into Park Rivulet, but the output for minimum flow would only be 1,000 b.h.p. The feasibility of diverting the Styx river into the Plenty catchment is now being investigated, and it has been discovered that a basin suitable for storage purposes exists at about 700 ft. above sea level. Some large storage is essential in order to equalize the flow, and unless this can be made available economically there is no future for the Styx catchment as regards power.

NORTH OF ENGLAND.

We are now well into 1921, and there has been no indication of any improvement in the metal position. Lead and zinc have reached a level that roughly corresponds with that of 1914, but the value of concentrates is of course relatively lower. Galena of 80% Pb is worth about £8, while lead is £19, but blende is really unsaleable. I saw one formula offered recently which gave a *minus* value of 23s. 6d. per ton for 50% ore, with spelter at £25. In this case the formula gave a considerable improvement with spelter at, say, £40, and at that level most mines would be able to produce. The smelters do not think that lead can remain at anything like the present low price and there is a certainty of an appreciation. It is, how-

ever, impossible to anticipate when this will occur, and mine managers tell me that they cannot work with lead at under £35. This of course implies the existing ratio of cost. A permanent recovery depends largely on coal. A substantially lower price for coal would affect the mines immediately in two directions, that is, the actual cost of fuel, and the lower returning charge payable to the smelters. The first reduces the cost of production; the second raises the value of the concentrates. But with the present coal strike it is impossible to look far ahead at present. The principal factor is, however, labour, and recently there has been a more striking alteration in the attitude of the Union leaders. Up to recently the men have been under the impression that the owners had some inexhaustible reserve from which to draw, and that wages could be paid whatever the price of concentrates. They now see the results of their demands, in the virtual suspension of the lead industry, and they realize that their members are out of employment, with but little hope of re-engagement. I suppose that the whole situation has been carefully considered, as the owners are now, for the first time, receiving the active co-operation of the Union in the reinstatement of the industry. It is realized that wages must come down, and that no longer can the men be transferred to more lucrative employment, that half a loaf is better than no bread, and that it is now a case of saving the ship. Several instances have come to my notice that confirm this, where the Union officials have unhesitatingly accepted the principle of lower wages, on the grounds that wages can only be payable out of production, and that the "cost of living, with an improvement in the standard of life" basis, must be abandoned for the moment.

The officials of one of the largest unions connected with our industry came down to a local mine, and, quite frankly, advised the men to accept a large reduction in wages, and indeed to accept the principle of a minimum wage on a really low basis, if the company would devise some system by which an automatic rise in wages would take effect when prices improved and the cost of production became lower. He pointed out to the men the importance of reducing costs in every direction, *by better work*, and stated that the "ca' canny" idea was suicidal. The management was much impressed by this new attitude, and agreed to consider a scheme of the nature indicated.

Managers must not altogether found their hopes on a rise in prices; they must concentrate on reducing the cost of production. Too often this is confined to the idea of better mechanical methods, involving heavy capital expenditure, but I venture to submit that it is far more important to reorganize the system of employment, and to get the men really interested in their work. The potential savings in this direction are enormous. As an illustration which shows the margin of saving, I may instance what occurred recently in a large mine. The contracts were cut 20%, and in the next succeeding pay, the average daily wage was as high as the previous month. Labour conditions and labour ideals must now be studied as an essential part of mine management, and I believe that with these satisfied, the cost of production can be enormously reduced.

The Mine Owners' Association met in London recently, and there was naturally a feeling of intense depression, some members even going as far as to suggest that the Association should be disbanded, but this was promptly overruled. This year will undoubtedly be the worst that has ever been experienced, and it is more than ever important to stick together. Many of the members feel that there should be co-operative selling of concentrates, and at the meeting in June a scheme may be brought forward. A large buyer of blende told me that he would not entertain buying small parcels, and pressed upon me the importance of offering a continued output. The Swansea smelters have always stated that if they had a substantial supply of blende, they would gladly give a higher price. They want security for raw material, and little odd lots are obviously no good to them. The same rule applies to galena, and if even a proportion of the mines combine, it would be to the advantage of both the owners and the smelters. A meeting of the Industrial Council was held the same afternoon, and the Union members showed a spirit of co-operation that certainly was an immense encouragement to the owners. It was the best meeting that we have held, and will lead to great things if we can continue to look upon the industry as a joint interest of men and owners. The names of Mr. Anthony Wilson and Mr. J. L. Francis were suggested to act as owners' representatives on the Board of Trade Consultative Committee for Non-Ferrous Mines. I hear that Mr. Bridgeman has asked Mr. Wilson to undertake this duty, and that Mr. James Wignall, M.P., has been appointed to the Committee to represent the labour side.

As to the mines themselves, they are practically all stopped or stopping. At Thornthwaite the mine is being kept clear of water, and two ends are being driven, the directors having decided to continue this small programme in the

hope of better prices, failing which the mine will be dismantled. Threlkeld mine is now stopped as a producer, and all the men have been dismissed, except 10, who are engaged in carrying through a ventilation level. There are happily no pumping charges, and the mine will re-start directly prices improve. There has been a general reduction of 12s. per week at both these mines, and the men have expressed a general desire to start work directly there is any substantial improvement in the value of concentrates. At Greenside mine the liquidation continues, and the lower rate of wages has been accepted, but unfortunately the drawing and dressing of the crude ore in stock has been suspended for the present. A higher price for galena will enable the work to be resumed, as there is still a large tonnage of broken ore to treat. I am afraid that the Vieille Montagne Zinc Co. have decided to permanently close down the mines in the Alston district. This is a great blow to the industry, their production of blende being by far the largest in the country. A small programme of development is being pursued, for this year, at Nentsbury mine, in the hope of finding new deposits; if successful it might affect the situation.

The position at Wanlockhead and Leadhills is critical. Despite all conciliatory influences, including, strange to say, a visit from Mr. Smillie, the men refuse to accept a reduction in wages. The cost of pumping at these two mines is approximately £3,000 per month, and unless the men agree promptly to a substantial reduction in wages, the mines will be flooded, which would mean the extinction of the industry in that area. I sincerely hope that the men will not persist in their unreasonable attitude, as a temporary period of low wages might carry the mines through the crisis, and they would then have the opportunity of participating in better times, if these come.

In the Weardale area, Boltsburn and Sedling mines are both working, but at a very large reduction in wages. I am glad to learn that the men accepted the necessary change in a most friendly spirit, and at lower wages they are putting increased energy into their work. The quarries in this valley are practically closed down for the present, as the products, ganister and limestone, are principally required for the iron and steel works in the Durham area. Lord Allendale's mines are still at work, and I understand look well. I hear that Mill Close mine in Derbyshire is still producing, and that the workings look very well, but I have no direct knowledge.

There are no mines producing in Wales. East Halkyn is closed down, and at the famous Halkyn mine I believe that one level is being driven. Continual negotiations are taking place over the tunnel scheme, but there seems no immediate probability of a settlement being reached. It is more than ever difficult to understand why all parties cannot sink differences and come to a working arrangement. The Shropshire mines are practically closed down for the present, but this is merely temporary, the demand for barytes being very poor just now.

I hear that the Swansea zinc smelters have by no means given up hope of a revival of this industry, and that some of the works are now engaged in repairs and improvements to the plant. The hope is that by the end of the year there will be much higher prices, and that lower costs will enable them to resume work. A small cargo of Australian zinc concentrates has been delivered at Antwerp at a freight charge of 45s.; with the original cost of £4. 10s. at Port Pirie, the cost, as far as these charges, would be £6. 15s. for 47% ore. I cannot learn that the Board of Trade has fixed any basis for the sale of their huge stocks of ore which still hang over the market.

PERSONAL.

The firm of PHILIP ARGALL & SONS, of Denver, has been dissolved.

RALPH ARNOLD has been on a short visit to London from the United States.

W. BARAGWANATH has been appointed Director of the Geological Survey of Victoria.

GEORGE BARGATE, late of Dolcoath, has been appointed superintendent for the Central European Mines, Ltd., Jugo-Slavia, for which Bewick, Moreing & Co. are the general managers.

JAMES P. BEST is returning from Nigeria.

EDGAR BONDS is expected from West Africa.

PROFESSOR J. S. S. BRAME has been elected president of the Institution of Petroleum Technologists.

A. R. CANNING has left for Nigeria.

W. A. CARLYLE has returned to London from Canada.

E. H. CLIFFORD has resigned as consulting engineer to the Central Mining and Investment Corporation.

J. A. DUNN, of the Bendigo Amalgamated Goldfields, has been elected to a Frecheville Research Scholarship at the Royal School of Mines. He is making a petrological study of the rocks at Mount Bischoff before coming to England.

J. C. FARRANT, London manager for the Hardinge Company, was married to Alice Christine Gaskell on April 7.

DR. J. S. FLETT has been elected president of the Geological Section of the British Association meeting to be held in September.

W. F. GARLAND has retired from the secretaryship of the Mysore Gold Mining Company after serving in that capacity for twenty years, and has been elected a member of the board.

W. H. GOODCHILD has gone to Spain.

S. V. GRIFFITH has joined the staff of the Corocoro United Copper Mines, Ltd., Bolivia.

A. A. HARRIS is back from Nigeria.

DR. F. H. HATCH has been appointed by the Secretary of Mines to be technical adviser to the department on questions relating to the metalliferous mining industry.

HYMAN HERMAN, engineer for briquetting for the Victorian Electricity Commission, is going to Germany to purchase briquetting plant for use at the Morwell brown coal deposits.

H. R. HILL has been appointed president of the Transvaal Mine Managers' Association.

ROSS B. HOFFMANN has returned to the United States.

J. VOLNEY LEWIS, head of the department of geology at Rutgers College, New Jersey, has been appointed first secretary to the Society of Economic Geologists, recently formed in America.

EDWIN LUDLOW is the new president of the American Institute of Mining and Metallurgical Engineers.

HAROLD D. MARTIN has returned from India.

E. P. MATHEWSON is here from the United States.

CAPTAIN A. H. MOREING is a member of the House of Commons Select Committee on Telephones.

H. L. MORTON has left for India to take up an appointment with the Bengal Iron Company.

EDGAR PAM has been appointed manager of the Modderfontein East.

G. S. PATERSON has returned from Peru, and has gone to South Africa.

W. PELLEW HARVEY has left for Australia.

J. S. PENBERTHY has joined the staff of La Compania Estanifera de Llallagua, Bolivia.

A. R. PENGILLY is now at Tampico, Mexico.

JOHN ROBERTS has gone to Mysore

E. G. ROBSON has gone to Venezuela.

HUGH ROSE is expected from Mexico.

R. A. RUSHA is expected from Nigeria.

HJALMAR E. SKOUGOR is here from New York.

DR. G. F. HERBERT SMITH has been appointed assistant secretary at the Natural History Museum, South Kensington.

DR. O. J. STANNARD has left on a short visit to the United States.

ARTHUR E. TAYLOR is on his way home from India.

J. B. TYRRELL is visiting the gas and oil regions of Alberta.

G. A. WATERMEYER, A.R.S.M., has been appointed professor of mining in University College, Johannesburg.

SIR TREVREDYN WYNNE has returned from Burma.

H. H. YUILL is back from West Africa.

W. E. THOMAS died last month from pneumonia.

S. R. BASTARD, director of several Nigerian tin companies, died last month.

D. T. WILLIAMS, a well known London analyst, previously connected with the South Wales metal industry, died last month.

HENRY BATTENS, lately manager of the Grenville mine, died last month. He was a Cornishman by birth and training. He spent many years in New Zealand, where he became manager of the Hauraki gold mine.

SIR ROBERT TAYLOR, head of the firm of John Taylor & Sons, died early this month. He was knighted last year in recognition of the firm's great services in connection with Indian mining.

The Mining World celebrated its fiftieth anniversary this month. We wish Mr. W. CHISHOLM, the proprietor and editor, many more years of prosperity.

TRADE PARAGRAPHS

THE GLOBE PNEUMATIC ENGINEERING CO., LTD., of 1, Victoria Street, London, S.W.1, and Luton, send us their new catalogue of pneumatic tools, including hand hammer-drills and rivetters

METROPOLITAN-VICKERS ELECTRICAL CO., LTD., of Manchester and Westminster, send us leaflets relating to three-phase transformers for rotary converters and transformers for use in collieries.

EDGAR ALLEN & CO., LTD, Imperial Steel Works, Sheffield, send us their *Edgar Allen News* for March. This contains notes on the application of magnetite for iron and steel making and the prevention of fitchering of drill steels.

THE GENERAL ELECTRIC COMPANY, LTD., announce their approaching removal to a new building erected for them in Kingsway, London, W C.2, and named Magnet House. The show-rooms will remain at Queen Victoria Street. They also send us their circular O.S. 2465 relating to their Osram miners' hand lamp.

VICKERS PETTERS, LTD., of Ipswich, send us an elaborate catalogue relating to their Semi-Diesel Crude Oil Stationary and Marine Engines. Among the novel features may be mentioned the new electrical starting apparatus. The London offices of this company are being moved from Great Portland Street to 75b, Queen Victoria Street.

THE MOND NICKEL CO., LTD., have been giving cinematograph shows at their offices, 39, Victoria Street, Westminster, illustrating the operations at their Sudbury mines and at the Coniston smelters. Mr. Robert Mond, Chairman of the company, kindly gave most interesting descriptions of the work done and of the business of the company when a special show was given to representatives of the press.

METAL MARKETS

COPPER.—Although early in March the market was easy, in the latter part of the month things took rather a firmer turn, this remark applying to both standard and refined metal Some purchases of standard were entered into some time ago on American account, and because there were fears that the warrants might be taken up when such contracts matured, and as there is comparatively little rough copper in store, bears became rather anxious to cover their open positions and a good demand ensued for intermediate dates The result has been that standard copper values came very close to those of refined. Latterly a more hopeful feeling was engendered in the general situation by the reports of further curtailment in America. It is understood that not less than ten producing companies are ceasing production, including Anaconda, Utah, Ray Consolidated, Chino, and Nevada Consolidated. It is not surprising that producers have got tired of turning out their copper at a loss, and this rather drastic cut in production should eventually improve the situation. Meantime there are still the very large accumulations on hand to be disposed of. It seems that in spite of recent curtailments production continued in excess of consumption, and that the accumulated stocks have increased considerably since the end of the year. Consumption everywhere is unsatisfactory.

Average price of cash standard copper: March 1921, £67. 13s. 3d.; February 1921, £71 0s. 9d.; March 1920, £109. 11s. 10d.; February 1920, £120. 6s. 2d.

TIN.—The general position of this metal shows no material alteration. The price-pegging policy has been

abandoned in the Straits, but the fact remains that a considerable accumulation of tin exists in the hands of the Federated Malay States Government. In regard to this it is understood that the authorities in the Straits have come to an agreement with those in the Dutch East Indies that their respective stocks shall not be thrown on the market, this understanding to remain in operation to the end of May, when presumably matters will be reconsidered. This announcement did not have any particular effect upon the market, for the reason that it had for some time been understood that the F.M.S. Government had not intended sacrificing their stocks at a loss, and in any case the agreement does not refer to current production. In the meantime, business has been initiated once more in the Straits and also with Batavia, although no great quantities appear to have changed hands in either quarter. So far as demand is concerned this has been very unsatisfactory. Only a very small business has been doing with home consumers, as is understandable in view of the slackness of the tinplate trade America has done a little business now and then, but nothing to speak of, while Continental demand has also been restricted. A factor which should not be lost sight of is the possibility of a 10% ad valorem duty being imposed on imports of tin into the United States. If this tariff were definitely decided upon it might create some demand for metal now in this country to be shipped over there in order to get in before the duty is put on. In the meanwhile, however, world supplies are ample, and consumption poor, and for that reason it is difficult to see any big price advance in sight. At the same time, at the current comparatively low level of values operators are cautious in selling short. During the month of March the prices fluctuated without any very definite tendency.

Average price of cash standard tin: March 1921, £156. 4s. 7d.; February 1921, £166. 9s. 1d.; March 1920, £369. 14s. 5d.; February 1920, £395. 16s. 6d.

LEAD.—Values of this commodity recovered somewhat during the month of March from the comparatively low level touched towards the end of the previous month. It is difficult to give any very definite reason for the improvement, except that the low level referred to appeared to attract dealers, and also to some extent consumers, with the result that prices improved. Speaking generally, however, the quantities going into consumption remain exceedingly restricted, while supplies of metal are steadily coming forward. A certain amount of speculative interest has been seen in the market, possibly based upon the hope that the reduction in the bank rate which is expected will be the means of stimulating trade and giving a greater outlet for the metal. In regard to stocks abroad, there is no definite news as to how much is held in Spain, but a good quantity is believed to be there. The new reparation proposals in regard to Germany might be the means of retarding further supplies from there, but these were not, after all, an important factor in the situation. A feature recently has been further arrivals from Belgium. Australia virtually remains out of the picture so far as lead supplies are concerned. The American market has shown a fluctuating tendency. It is believed in some quarters that the duty on imports into the United States might be raised, in which case some shipments from here might take place with the object of getting the metal into America before the increase takes place. It is possible that some of the firmness seen in the market here was due to such anticipations.

Average price of soft pig lead: March 1921, £19. 2s. 9d.; February 1921, £21; March 1920, £47. 1s. 9d; February 1920, £50. 12s. 9d

SPELTER.—Business in this article with the consuming trades was a little brisker during the month of March, but the takings of consumers still remain very restricted. At one time some anxiety was felt in regard to supplies from Germany. It was feared that the new reparation proposals, whereby 50% of the value of such imports have to be paid to our Government, would be the means of stopping supplies, and as a consequence the market showed considerable firmness. However, fears in regard to the immediate future were dispelled by the announcement that purchases made prior to March 8 and arriving before April 15 would be exempt, and with certain quantities coming forward from Germany, values eased off. So far as future offers from Germany are concerned it is difficult to see exactly how matters will shape themselves. In the meanwhile little has been offering from that quarter, but some business has been done both with Scandinavia and Belgium. Only limited quantities appear to be procurable from the latter coun-

try, as they are by no means pressing sales. So far as America is concerned that country has not been a factor in this market one way or another. The future of the market here is very obscure. This country has been relying largely for some time past on German supplies, and the market here has been practically based on the price at which Germany offered. It would be natural to suppose that the new 50% regulation, already referred to, would be the means, if anything, of restricting offers from Germany, or at least of making their prices higher, but whether such apprehensions are felt or not the market so far has not reflected them materially.

Average price of spelter: March 1921, £25. 10s. 5d.; February 1921, £25. 5s. 5d.; March 1920, £54. 16s. 7d.; February 1920, £62. 3s. 6d.

Zinc Dust.—The market is quiet and prices are easier. High-grade Australian stands at about £55 per ton upwards, American at £57. 10s. to £62. 10s., and English at £60 per ton.

Antimony.—The price of English regulus remains at £37 to £40 for ordinary brands and £38. 5s. to £42 for special brands. Foreign regulus on spot is quoted at £23. 10s. to £25 per ton in warehouse.

Arsenic.—The market is stagnant, Cornish white being nominal around £48 to £50 per ton delivered.

Bismuth.—The chief interest continues to quote 7s. 6d. per lb.

Cadmium.—The market is quiet, with the quotation 6s. to 6s. 3d. per lb.

Aluminium.—The price has kept steady of late at £150 per ton for both home and export.

Nickel.—£200 per ton is quoted for both home and export business.

Cobalt Metal.—Business is quiet, and the present price is 19s. per lb

Cobalt Oxide.—Black oxide is quoted at 16s. and grey at 17s. 6d.

Platinum and Palladium.—Manufactured metal (sheets and wire) is quoted at £19 per oz., but raw platinum in substantial parcels is obtainable around £17 per oz., and palladium at £15.

Quicksilver.—The market is quiet and without any special feature. The price has kept steady at £12. 10s. to £12. 15s. per bottle.

Selenium.—Business is quiet, with 10s. 6d. to 13s. per lb. quoted by sellers.

Tellurium.—There is no change in the quotation, which continues at 90s. to 95s. per lb.

Sulphate of Copper.—The tendency recently has been weaker, the present price being about £34 per ton.

Manganese Ore.—The market is quiet and weak, the latest quotation for Indian grades being 1s. 4d. to 1s. 5d. per unit c.i.f. U.K.

Tungsten Ores.—There is practically no business passing in the market, and sellers are reluctant to sell at less than 13s. 6d. to 14s., although buyers' ideas are below these figures.

Molybdenite.—85% is quoted at 55s. to 65s. per unit c.i.f. U.K.

Chrome Ores.—The quotation for 48% is £5. 10s. to £6 per ton c.i.f. U.K.

Silver.—Spot standard bars opened the month at 32½d., declined to 30⅝d. on March 5, and then recovered till 34⅛d. was reached on the 22nd. The quotation later receded, however, and the price on March 31 was 33⅛d.

Graphite.—The price of Madagascar 80 to 90% is £20 to £25 per ton.

Iron and Steel.—At the beginning of March the Cleveland ironmasters brought their selling price down by about 45s. per ton, making No. 3 Cleveland 150s. for home and 155s. for export. This reduction was followed by other makers, but did not do much to stimulate consumption, and production has had to be drastically curtailed. In the finished iron and steel branches, the amount of new business which has been passing during the last month has been very small, and works have been only able to carry on to a restricted extent. The Continental works too are badly off for orders and have been forced to make severe cuts in their prices in order to secure what business was about. In this country, certain price reductions have been made, but prices are still far too high to permit of a revival of good trade. The coal position looks like dealing a further disastrous blow to the iron and steel trades, the extent of which it is impossible to estimate at the time of writing. In spite of it, however, Cleveland ironmasters, early in April, made a further cut in their prices of 30s. per ton, thus bringing the price of No. 3 to 120s. per ton for the home trade.

THE MINING DIGEST

A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

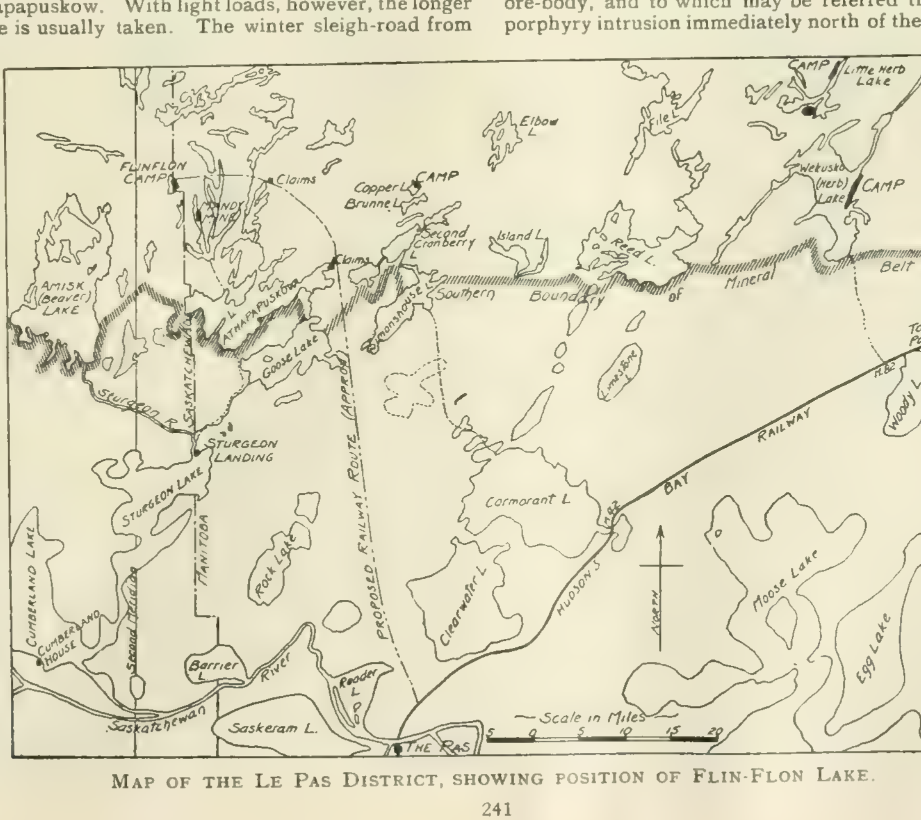
In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also notices of new books and pamphlets, lists of patents on mining and metallurgical subjects, and abstracts of the yearly reports of mining companies.

THE FLIN-FLON ORE-BODY.

The February *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper by R. C. Wallace, Commissioner of Northern Manitoba, on the Flin-Flon copper ore-body, which is now being developed. This mine is situated north of Le Pas, Manitoba. A number of references have been made in these columns to this enterprise, the most recent being by Mr. Wallace in the December issue and by E. L. Bruce in October last.

Flin-Flon Lake is distant by air line 68 miles north-north-west from The Pas, through which town the Canadian National Railway passes en route for Hudson's Bay. The Pas is the distributing centre on the Saskatchewan river for the mineral field and for settlements on the Hudson's Bay railway. The summer route from The Pas is by way of the Saskatchewan river to Sturgeon Landing, which is the head of the navigation for steamboat traffic, and thence by canoe to Flin-Flon Lake. The total distance is 130 miles by steamboat and 60 miles by canoe, a total of 190 miles from railway communication. The canoe route can be shortened by using the summer road built by the Provincial Government from Sturgeon Landing to Lake Athapapuskow. With light loads, however, the longer route is usually taken. The winter sleigh-road from The Pas is approximately 90 miles long. The property is near the well-established and historical canoe route from Cumberland House northwards through Lake Athapapuskow and the Pine Root River to the Churchill River at Pukatawagan. The camp lies nine miles west of this route in a territory which was hitherto not frequently travelled between the Pine Root River valley and the Beaver Lake country.

The ore-body lies in amygdaloidal greenstones which are to be referred to the earliest volcanic flows in this district. They have been named by E. L. Bruce, of the Geological Survey, the Amisk volcanics, owing to their prevalence in the vicinity of Amisk (Beaver) lake. Associated with the greenstones, and probably somewhat later in age, although earlier than the granite intrusions, are quartz-porphyries which are parallel in strike to the greenstones and which do not here display clear-cut intrusive relationships into the greenstones. There are also lamprophyric dykes which are apparently earlier than the intrusions of granite, probably earlier than the quartz porphyry flows, though later than the amygdaloidal greenstones. The later granite, which is found one mile south-west of the Flin-Flon ore-body, and to which may be referred the granite-porphyry intrusion immediately north of the ore-body,



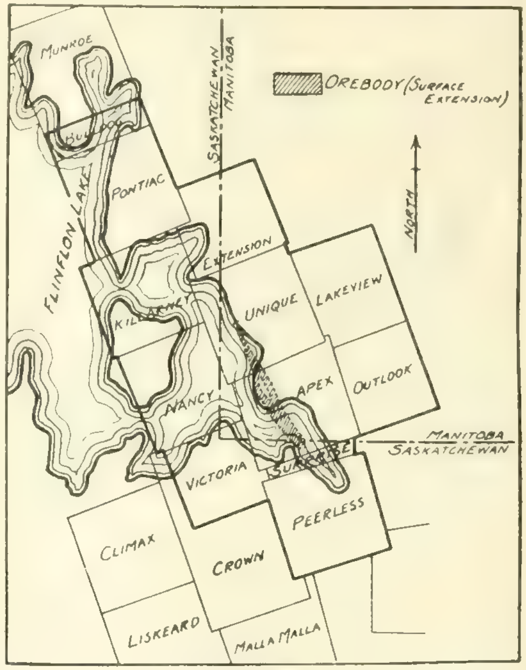
MAP OF THE LE PAS DISTRICT, SHOWING POSITION OF FLIN-FLON LAKE.

has been named by Bruce the Kaminis granite. This granite is intrusive, not only into the volcanics referred to, but also into sediments that overlie the volcanics, but which are not exposed in the immediate vicinity of the Flin Flon property. The Flin Flon and other sulphide deposits of this district, as well as the gold deposits in the quartz veins, are to be referred to this granite as ore deposits representing deposition at lower and higher temperatures respectively.

During the process of shearing, which probably occurred in the earlier stages of the eruption of the Kaminis granite, the quartz porphyry offered greater resistance to the shearing forces than did the amygdaloidal greenstone. In the greenstone itself there are apparently units of greater resistance than others. In all probability the zones that suffered intensive shearing represent a volcanic tuff interbanded with the more massive lava flows. In the process of replacement by sulphides the more sheared zones have suffered much greater change than have the more massive members.

The ore-body, which skirts the south-east shore of the lake, strikes with the country rock and dips approximately 70° east. From the records of diamond-drill holes at the south end of the deposit, it would also appear that the ore-body pitches at a low angle to the south. Horses of unmineralized greenstone separate the ore-body into more or less independent lenses. At the south end of the ore-body a massive greenstone has been less affected by weathering than the sulphides, and stands out as a prominent topographical feature on the property. It would seem, from the, as yet, incomplete drilling at the south end of the deposit, that this horse forms part of a crescent-shaped mass of greenstone open toward the south. The deposit has a known length of 2,593 ft., and has been proved to a depth of 900 ft. over a length of 1,000 ft. Its greatest width transverse to the dip is 400 ft. This figure includes some narrow horses of greenstone. Its greatest transverse width at the 900 ft. level is 35 ft. From the results of diamond-drilling and underground development work, the total tonnage has been calculated to be sixteen million, exclusive of the horses of greenstone in the ore-body. This estimate makes no allowance for possible ore under the 900 ft. level or possible ore at depth in the line of pitch at the south end of the ore-body. On the whole, the ore-body is most compact at the north end and shows a tendency to intermingle with inclusions of considerable widths of country rock towards the south end at depth.

The minerals of the ore-body are, in order of importance, pyrite, zinc blende, and chalcopyrite. Gold and silver are apparently associated mainly with pyrite, the silver in all probability in the form of a mixed silver sulphide. Galena has been found in vugs in the otherwise unmineralized rock, but does not occur in quantity in the ore-body. Native copper is found in leaf form as a secondary product in the upper sulphide zone. For practical purposes the ore is divided into two types: first, solid sulphides; second, disseminated ore. The solid sulphides occur in the centre and toward the hanging wall of the ore-body, and are in places in direct contact with the hanging wall. As a rule, however, a selvage of disseminated ore separates the solid sulphides from the hanging wall; while on the foot-wall there is found invariably a considerable width of disseminated ore. The hanging wall disseminated ore is found to carry smaller percentages of copper and a greater proportion of gold and silver than the disseminated ore on the foot-wall; in other words the deposition of pyrite is more extensive on the hanging wall side of the ore-body, and the deposition of chalcopyrite is more extensive on the foot-wall side. As far as has yet been ascertained the same holds true (though to a lesser degree) with the solid sulphide, which gives the higher values in copper on the foot-wall side. The solid sulphides are broken by masses of unmineralized rock and the contact between solid ore and rock is, generally speaking, sharp; as a rule, also, contact between disseminated ore and sulphide is distinct, though in the underground workings a distinct gradation may be noted in places. The richest copper ore in the deposit is found in the disseminated foot-wall ore which gives values of from 3% to 5% copper, the copper values for the whole ore-body, exclusive of horses, being approximately 1·9%. A thin selvage of blende separates the solid sulphide from the disseminated ore on the hanging wall side. Zinc, which averages approximately 3·8% for the whole ore-body, is more abundant on the hanging wall side

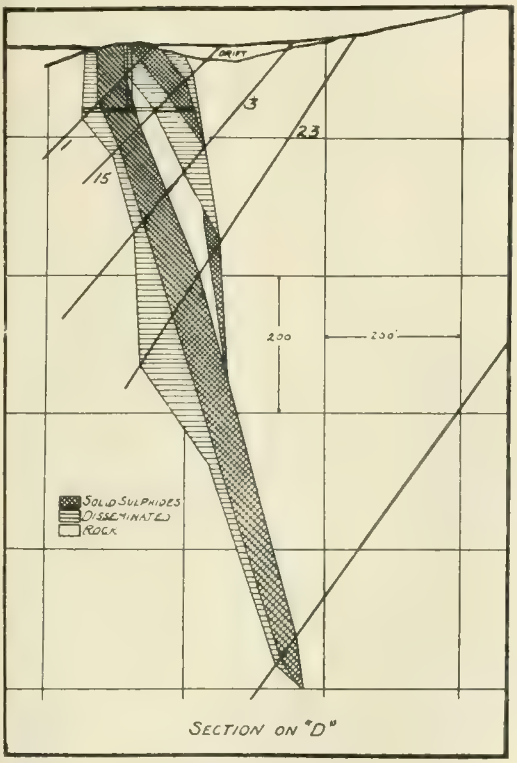


CLAIMS AT FLIN FLON LAKE

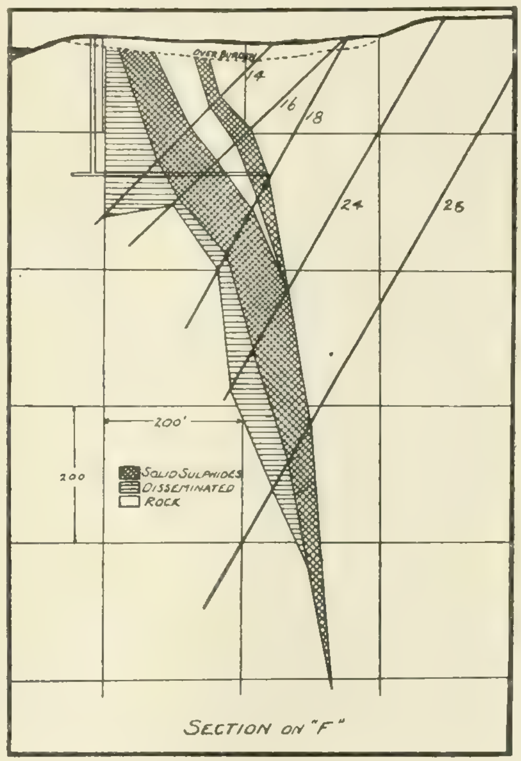
than elsewhere. While it might be expected that the gold would increase and the copper and zinc would decrease in depth, no indication of any such variation has been noted to the depth at which diamond-drilling has explored the property.

The ore-body has been formed by replacement of the rock which had already undergone intense mineralogical alteration during the shearing process. Where rock still remains (as in the disseminated-ore areas), its mineralogical composition would indicate that, in the main, the replaced rock was basic in character. The richest disseminated ore exposed by underground operations occurs in a typical chlorite schist. Bodies of quartz-porphyry occur, however, in close proximity to, and apparently within, the ore-body. At the end of the cross-cut of the No. 2 workings, quartz-porphyry forms the hanging wall in contact with the disseminated ore, the contact being practically vertical, while the dip of the rock in the ore-body is from 70° to 75°. In the disseminated ore immediately west of the solid sulphides in the east end of the same cross-cut, highly silicious bands, which represent either a silicious rock of

quartz-porphyry type or a subsequent infiltration of silica during the process of mineralization, are found. That silica has, to some extent at least, been associated with the replacement, is indicated by the character of the rock that has been exposed by surface workings immediately east of the horse. Here the sulphides have disappeared through weathering, and there is left a highly porous pumiceous silica rock which would appear to represent the result of silicious infiltration and replacement into a rock that was probably of an acid type originally. The bands of silicious rock in the disseminated ore in the cross-cut are of a similar character. The extent of shattering that the rock has undergone on shearing has been a factor of greater importance in facilitating replacement than has the actual chemical character of the rock itself.



SECTION NEAR NO. 2 SHAFT AS DETERMINED BY DIAMOND-DRILLING.



SECTION NEAR NO. 1 SHAFT AS DETERMINED BY DIAMOND DRILLING.

Replacement has taken place at a fairly high temperature and by hydrothermic processes; on the foot-wall particularly, the rock has been highly sericitized. In the chlorite schist, and in the sericite schist as well, irregular masses of talc are encountered in the underground workings. While such mineralogical changes indicate hydrothermal deposition, it is a remarkable feature in connection with the ore-body that the contact between solid sulphide and unmineralized, unchanged greenstone is so distinct, as is actually shown in the cross-cuts. While both quartz-porphyry and lamprophyre are rather closely associated with the deposit, there is no evidence to show that either volcanic phase is connected with the deposition of sulphides. The Kaminis granite and its offshoots seem to be the parent body from which the hot solutions and the vapours emanated. Throughout the district, sulphide bodies frequently occur in close association with quartz veins carrying gold; elsewhere, however, the sulphides are pyrite, with relatively small percentages of pyrrhotite and only occasional chalcopyrite. It would appear that during the later stages of plutonic activity now represented by the granite, the deposition of sulphides was closely connected with the precipitation of a gold-carrying quartz.

In the summer of 1915, the Mosher-Creighton party, which had been working north-east of Amisk Lake, was guided, by information, to the Flin-Flon Lake district and the Flin-Flon ore body was discovered. Some surface trenching was done in order to obtain an idea of the size of the ore-body, and late in the summer the claims were recorded. The news of the discovery and the importance of the ore-body were appreciated by other prospectors, and in a very short time the whole country in the vicinity of the deposit was staked.

During the winter of 1915-16, work was confined to surface sampling and cross-trenching. In March, 1916, two drills were at work, and by July of the same year 6,000 ft. of drilling had been done by New York and Boston interests, who, however, failed to reach an agreement with the owners. In the spring of 1917 certain Toronto interests entered into an agreement and diamond-drilling was continued throughout the year and until July, 1918. In all, 44 holes were drilled, representing a total linear footage of 25,664 ft. In March, 1920, an option on the property was taken by New York and Canadian interests, and since that date two shafts have been sunk over 500 ft. apart at the south and north

ends of the main horse The first shaft has reached a depth of 200 ft and at that depth there is 210 ft. of cross-cutting and approximately 100 ft. of driving southward. It was expected that the shaft would be entirely in the foot-wall, but at a depth of 135 ft. disseminated ore was encountered, and the shaft was continued in this ore to the 200 ft. level. When the cross-cutting is complete it will expose approximately 100 ft. of solid sulphides. No. 2 shaft was sunk to the 100 ft. level, and a cross-cut approximately 165 ft. long was made at this level. Sinking is now being continued to the 300 ft. level. (These figures refer to the situation as on September 10, 1920).

In operating the Flin-Flon property, a very large low-grade ore-body, far removed at present from transport facilities and industrial centres, there are many problems of major importance to be solved ; these refer in particular to water-power facilities, metallurgical processes, availability of fluxing material, fuel, and transport.

In order to develop water-power in sufficiently large quantity for operating a mine and smelter of 2,000 tons capacity at the Flin-Flon property, two sources of power are available. One of these is on the Churchill River at Island Falls, and is distant some 60 miles. A minimum production of 80,200 h.p. has been estimated for this fall. A nearer source of power, which will in all probability be adopted, is Birch Rapids on the Sturgeon-Weir River, distant 35 miles from the property in a westerly direction. The minimum under present conditions is 3,270 h.p., but this may be increased at will by tapping the Churchill River at Frog portage at the headwaters of the Sturgeon-Weir water system. At periods of high water there is at the present time a natural flow of surplus water from the Churchill River into the Sturgeon-Weir system and thence into the Saskatchewan River. It is estimated that the available power can be increased to 20,000 h.p. by thus utilizing part of the flow in the Churchill basin.

The disseminated ore will offer no special difficulties in treatment. Generally speaking, it will concentrate fairly readily and will be smelted in the reverberatory furnace. The solid sulphide (mixed pyrite-chalcopyrite-blende) ore will present greater difficulties to the metallurgist. Experimental work may discover a method of concentration whereby it may be possible to recover all or the major part of the zinc. If this is not feasible, it will doubtless be treated in the blast-furnace by pyritic smelting and only a limited proportion of the zinc recovered. There is a great field for experimental work on this ore in order to devise the most suitable and economical method of handling and smelting the solid sulphides. It will be necessary to add silica in considerable proportions and limestone in small amounts to the ore before smelting. Quartz veins that carry gold are more numerous on the west end of the mineral belt (Beaver Lake) and at its east end (Herb Lake) than elsewhere throughout the belt. The eastern district in particular is somewhat remote from the property. Apart from the gold-bearing veins there are silicious bodies of other types in the mineral belt ; in particular, quartz-porphyry flows, felsitic intrusions into the earlier volcanics, and sediments with a high silica content. In all probability quartz flux will be obtained in part from the lean bodies of greater extent and closer proximity to the deposit. Magnesian limestones of Ordovician age occur in quantity within ten miles of the ore-body. Pure limestones of Upper Devonian age are exposed at the north-west end of lake Winnipegosis. The use of this would necessitate a rail haul of 250 miles to the property.

Owing to the great distance from the eastern areas, Western coal will doubtless be utilized as fuel for the smelter. The success which has attended the use of pulverized coal in the experiments already carried out by various copper-smelting companies would indicate that powdered coal might be the cheapest and most available type of fuel for the smelter. It is not improbable, as well, that satisfactory electrical processes may be devised for an ore of this type many years before the deposit is exhausted. But at the present time development is more important than treatment.

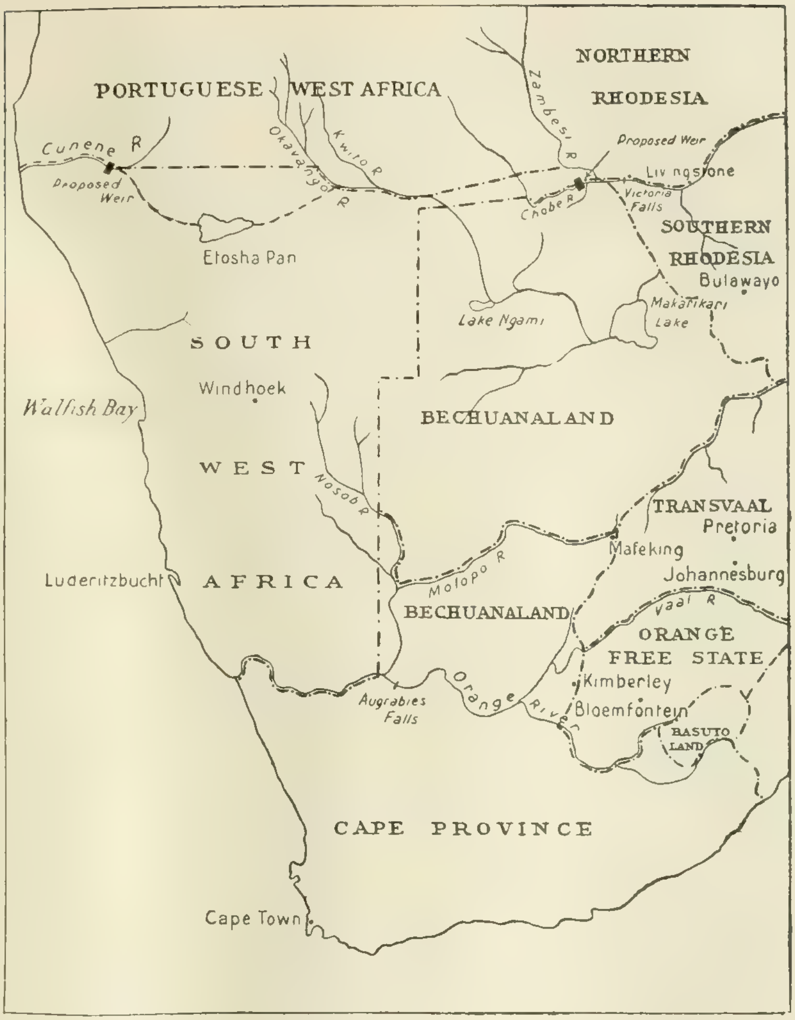
RECLAIMING THE KALAHARI DESERT.

Though the question of reclaiming the Kalahari Desert is not a mining problem, it is one of great direct interest to mining engineers, for if this and similar districts in Southern Africa were capable of supporting life a large accession would be made to the territories worth prospecting and development. Readers will probably be aware that Professor E. H. L. Schwarz has during the last year or two brought forward suggestions for the reclamation of these regions by bringing water into them so as to restore the old lakes. His scheme has already been discussed in the pages of the *South African Mining Journal*, *The Times*, and elsewhere. He has also published a book on the subject in Capetown. The Department of Mines and Industries of the Union of South Africa has taken an interest in the subject, and the *South African Journal of Industries*, published by this Department, has published an article by H. J. Choles in the January issue. We quote from this article herewith.

The question as to whether South Africa is drying up has often been asked and discussed. Whenever a drought occurs it invariably arises ; people refer to the reports of Le Vaillant, Lichtenstein, and other famous explorers of a century ago. They talk of the hippopotamus that infested the Karroo rivers, the rhinoceros, eland, and hartebeest that ranged through the forests along the banks, forests that have since given place to the prickly pear and Karroo bush ; and, pointing to the various circumstances that seem to indicate that South Africa is drier than it was a hundred years ago, they take sides in argument and endeavour to explain what is happening to the climate.

Two schools of opinion have thus evolved. According to the students of the one school, South Africa is, like other parts of the world, subject to cycles of dry and wet spells. The people who hold this view point to the literature of South Africa in the second quarter of the last century—roughly from 1827 to 1850—from which it appears that the conditions now prevailing are similar to those that prevailed at that time. They had then the same droughts, the same floods in the rivers, bringing down masses of mud instead of water, the same failure of harvests. So, it is argued, a spell of good years will come in due course, in accordance with the cycle of climatic changes.

The other school thinks differently. It maintains that, whether or no there be cycles in the weather, South Africa is actually drying up ; that gradually the sub-continent will become uninhabitable, the desert conditions begun in the Kalahari and in course of evolution in the Karroo, spreading eventually over the whole of South Africa, and driving the population to the relatively moist coastal belt, which on the south and east will offer the only areas fit for human habitation. Of this school of thought Professor E. H. L. Schwarz, of the Rhodes University College, Grahams-



MAP EXPLAINING PROFESSOR SCHWARZ'S PROPOSALS FOR RECLAIMING THE KALAHARI DESERT.

town, is one of the most able exponents, but his pessimism is relieved by the enunciation of a remedial scheme which, he claims, will not only stabilize the rainfall, thus rendering it of real value at all times to farming operations, but will increase it, and will also turn the Kalahari and the Karroo into rich regions capable of supporting a large farming population.

Schwarz's scheme is based on the fact that rainfall cannot occur without prior evaporation. The precipitation of moisture does not necessarily occur just at the spot where the moisture was taken up into the atmosphere, that is to say, over the sea or over a lake. It may occur a long distance away. Precipitation, or rainfall, depends upon the mountains or the changes in atmospheric temperature which are encountered by the current of moisture-laden air. Nowadays in South Africa rains come almost entirely from the evaporation that takes place over the sea. Unfortunately, however, as soon as the moisture-laden winds from the ocean reach the land, they encounter high mountains all along the coast; the moisture is precipitated as rain, and when the winds pass over the mountains they are almost dry; there is little rain for the interior. The ocean currents along the coasts, too, have an important influence upon the rainfall. It happens that the current along the east and south-east coast is warm, while that along the west coast is cold. The consequence is that the air which blows off the sea on to the land on the east arrives warmer than the land, and therefore, becoming suddenly chilled, lets its moisture fall; while the air blowing on to the land on the west comes colder than the land, it warms up, and is not only able to hold its moisture, but craves additional moisture to satisfy its increased power of absorbing water-vapour, in other words, it tends to dry up the land instead of supplying it with rain. The consequences are that, on the east coast, the coastal belt of Natal and Zululand, for instance, there is a good rainfall and a perennially moist atmosphere; while on the west coast there are hopeless deserts.

Evidence of the reason for thinking that these conditions are not stable, and that things are changing for the worse is found on studying the ancient lakes of South Africa. These are now almost dry; at best they are

swamps. And it appears that a proportion of the rainfall is due to the evaporation that is still going on from the remains of these lakes. Soon the last of these swamps will disappear, the desert will advance over the beds of these ancient lakes, and South Africa will be thrown back upon the sea as the sole source of its rainfall. Ages ago, and until quite recently, South Africa possessed three great lakes, covering some 50,000 square miles, an area equal to that of the Orange Free State, or to the three largest existing lakes in the Continent of Africa, or again to more than half the area of the five great lakes of North America combined (93,000 square miles). These three lakes are: Greater Ngami, covering 30,000 square miles; Makarikari, covering 15,000 square miles; and Etosha Pan, covering 5,000 square miles. These lakes have disappeared. The huge depressions which in a former age the waters occupied can still be traced; a few reedy, swampy "pans" are all that is left of these former inland seas.

In those days, as in Central Africa now, South Africa was independent of the seas for its rainfall; the lakes, with their great evaporative surfaces, provided the country with its own circulatory system, and South Africa, from the Zambesi and Kunene even down to Capetown, was like British East Africa in the luxuriance of its vegetation, its rich fauna, its ample rainfall, which with the hot sun sustained and encouraged all forms of tropical life. Then it was a country of great rivers, whereas now, the big rivers, on which the fertility of half the Continent of Africa depends, are in danger of extinction. The reason why the rivers are disappearing and the lakes have vanished is given by Professor Schwarz as headstream erosion, otherwise, the means by which the short, rapid coast streams eat back through the heart of the coastal mountains and tap the waters of the inland system, whose waters are more sluggish. Headstream erosion, again, has tapped the Zambesi basin, from the east, and has diverted its waters, which once flowed south-west, through the Kalahari, and has turned it into a desert. In the Transvaal, the Komati River is stealing into the territory of the Vaal River, the Olifants River draining inland as far as Pretoria, and the Limpopo reaching back even to the outskirts of the Kalahari. Further north, the Sabi River has pierced the Melsetter barrier-range and drains the whole country from Bulawayo to Salisbury; finally, the Zambesi sends back its tentacles almost to the west coast. Every one of these rivers started originally at the coastal rampart and has eaten back by headstream erosion. The waters inside the barrier-ranges once flowed toward central South Africa, and made the central depression a land of running rivers and of great fertility.

The continent is almost entirely girdled by mountains or tablelands that begin to rise sometimes actually at the coast, in other places at but a short distance from the seaboard. Professor Schwarz shows how the courses of these rivers have been changed; how the Congo River, which now empties itself into the Atlantic Ocean on the west coast, in ages past flowed steadily northward, through luxuriant country which is now the Sahara Desert, into the Mediterranean.

South of the Zambesi, the greatest South African river of the present time is the Orange. It rises in Basutoland and, after taking a north-westerly course, it turns, and for the last 500 or 600 miles its general direction is westward. Taking a line northward to the Zambesi, to the Victoria Falls, and then a line across the continent to the mouth of the Kunene River, crossing on the way the Chobe and Okavango Rivers, it will be seen that there is an area of roughly 600,000 square miles without a river worthy of the name, a land of successive deserts, the true "Thirstland of South Africa." It is this area that Professor Schwarz's scheme is expected first to redeem by irrigation.

Just as Egypt has still its Nile and the Sahara once had its Congo, so in times past South Africa had a great central river, which Professor Schwarz calls the Proto-Orange. This river rose in the highlands about Tanganyika, and is now called the Loangwe River. This flows south-west and joins the Zambesi near Zumbo; thence it originally flowed up the channel of the Zambesi to Wankie, then across to the Soa Pan or Makarikari, to the Molopo River and out to sea by the Orange River. The Proto-Orange fed and drained the Central South African lakes, Ngami and Makarikari. It failed as a river south of these lakes owing to the capture of its headwaters by the headstream erosion process to which reference has been made.

Livingstone's idea of how the waters were turned northward was that a "cataclysm of nature" had opened the rent of the Victoria Falls and drained all the waters into the cleft. R. S. Fairbridge states that what caused the diversion was a shallow bar in the river formed by a storm-carried drift of reeds and brush.

The watershed between the Zambesi and the Orange Rivers is so flat, west of the Bulawayo—Johannesburg railway, that when there are heavy rains to the north, the surplus water drains south into the Kalahari, and when there are heavy rains to the south, the surplus runs north into the Zambesi. The long, wide, shallow, reedy depression in which this takes place is called the Tamalukan River, and about three generations ago a very wet season in the north washed a great bank of reeds and rubbish into the southern part of the Tamalukan, where it stuck, and thus prevented any more water draining south toward the Orange River. This explanation corresponds with evidence gleaned from Bushmen, from which it appears that prior to about 1820 the Soa Pan (a remnant of the old Makarikari Lake) always contained water, in which hippopotamus, crocodiles, and fish abounded. But suddenly, they say, the waters from Ngami ceased to flow; the lake dried up, and the dead fish and animals were devoured by vultures. Professor Schwarz points out that these statements correspond with the descriptions of the country before and after 1820. Before that year Le Vaillant, Van Reenen, and others described the country as being like British East Africa; directly after 1820 Thompson described terrible droughts, and thereafter all travellers tell the same tale with increasing emphasis on the droughts.

Professor Schwarz proceeds to consider the western side of the continent, in particular the Etosha Pan—the remnant of a permanent lake—and the Kunene and Okavango Rivers. These rivers, together with the Zambesi and several of the headstreams of the Congo, rise in the Angola Highlands. To the south lies Ovamboland, a plain some 70,000 square miles in extent. In former times this plain used to be flooded annually from the Kunene and Okavango Rivers. Nowadays not half of this area is flooded, and the portion receiving the flood-waters is becoming smaller every year. To the south again of Ovamboland lies the Etosha Pan, which used to be a permanent sheet of water fed by the Kunene River, which, instead of turning westward and discharging itself into the Atlantic, as it now does, continued on its southerly course and flowed into the Etosha Lake, which then drained off eastward into the Okavango. Here, again, the headstream erosion of a coastal river has beheaded the Kunene, drawing its waters westwards. Professor Schwarz points out that, in the times when the whole of Ovamboland was periodically flooded, the huge evaporative surface thus produced added

very considerably to the rainfall of Angola, which must, therefore, be becoming steadily drier, with effects upon the Kunene, the Okavango, the Zambesi, and to some extent the Congo. His scheme, he claims, will restore the rainfalls of Angola and so maintain and perhaps enhance the flow of these rivers.

As already stated, Professor Schwarz ascribes the aridity and semi-aridity that characterizes parts of South Africa to the non-existence of a rainfall circulatory system independent of the ocean, confined within the coastal rampart of mountains and high land, and having as its source large sheets of water in Central South Africa to serve as evaporative surfaces. In other words, he says the disappearance of the 50,000 square miles of lakes which formerly constituted the main source of South Africa's rainfall system has led to the present state of aridity. His proposal therefore is to take steps to restore the three great lakes. To do this two weirs are necessary; one on the Kunene River, at a spot which will result in its being diverted into its old flood channels; the other at the Nduala Rapids, on the Chobe River, which will then tend to flow south instead of north. Professor Schwarz does not in either case suggest that masonry weirs be built to begin with. He thinks all that is needful at present is a weir built of piles and filled in with rubble and branches. Weirs of this description will create the necessary diversion, and later it can be ascertained what permanent works are necessary really to perpetuate the diversion. Professor Schwarz is convinced that the diverted waters of the two rivers will find their ancient courses, clearing them out wherever sand has drifted into them and has filled them up.

It remains to describe the effects which the damming of the Kunene and Chobe Rivers would have upon South Africa. Given the southward diversion of the waters of the Kunene and Chobe into their ancient beds, the first results would be the filling of the old lake beds—the Etosha, the Ngami, and the Makarikari—not to their ancient limits, but to an extent sufficient to create large evaporation surfaces for the improvement of the South African rainfall. From the Etosha the water would pass eastward along ancient water-courses until it poured into the Okavango. The Chobe weir would throw the waters of these two rivers southwards, resulting in the re-establishment of the Ngami Lake, from which again the Makarikari would fill. When these lakes are full, the probability is that the overflow water would reach the Molopo, and its course to the Orange and the sea would then be assured. This conclusion cannot, however, said to be certain, as survey data are not available.

Professor Schwarz says that the water-vapour from the lakes will permeate the whole of South Africa within the ledge of the coastal mountains. The inland slopes of these mountains will give as copious springs as the seaward slopes; these will gather into rivers and flow into the Karroo, as they did till quite recently. By restoring the moisture in the air to the amount that existed in it before 1820, it is claimed that South Africa will reap the following benefits among others: (1) steady rains instead of sudden outbursts; (2) clearer water; (3) no veld erosion; (4) protection of surface by continuous vegetation; (5) no brak; (6) no need to irrigate, except for special crops. The climate over the whole of South Africa will be rendered cooler by day and warmer by night, the rainfall will increase, even over the Kalahari Desert, which will be converted into a reasonably habitable country, droughts and deluges will disappear, rivers now dry for the greater part of the year will develop a perennial flow, springs will not fail, forests will spring up, and the whole country will become again like British East Africa is to-day, though possibly with a lower temperature. The restoration of the lakes will increase the fertility of the land through which the re-established river or rivers will flow, and large blocks of land, capable of supporting thousands of settlers, will become available for irrigation. The Kalahari soils are rich and they only need water to render them highly productive.

PETROLEUM PRODUCTION IN VENEZUELA.

In the *Engineering and Mining Journal* for February 19 and 26, A. H. Redfield, of the United States Geological Survey, writes on the present petroleum activities in Venezuela and of the prospects of the industry.

There are two oil-bearing districts in Venezuela. One includes the basin of the arm of the sea known as Lake Maracaibo, and the second comprises the shores of the Gulf of Paria from the northern part of the Orinoco delta to the promontory of Paria. The total area of the Maracaibo district is 27,500 square miles; that of the Paria region is 2,100 square miles. Only a small part of the oilfields about Lake Maracaibo has been proved by drilling. The Paria district has been celebrated for years for the production of asphalt, but no oil in commercial quantities has yet been extracted there.

The geology of the Maracaibo oil region, as far as it is known, presents similarities of stratigraphy and structure to the Colombian oilfields, particularly those of the Magdalena-Santander district, to which it is geographically contiguous. The mountains of the Maracaibo district are apparently a topographic and a geologic continuation of the Colombian Andes. As in Colombia, the manifestations of oil are most abundant in the Cretaceous sandstones and limestones and in the Tertiary, especially in a "coal series," the Cerro de Oro terrane, ascribed to the Miocene, though its Colombian counterpart has been considered Oligocene. An equally striking similarity of stratigraphy can be traced between the formation of the Maracaibo and Paria districts of Venezuela, and also between the formations of the Paria district of Venezuela and those of Trinidad. A continuity of structure is apparent throughout the three regions. The minor anticline folds with which the geosynclinal basin of Lake Maracaibo is wrinkled bear about N. 61° E. In the Paria region the prevailing structure is one of minor folds and faults with a general bearing of N. 75° E.

The Venezuelan oil is prevailingly asphaltic. Discoveries of paraffin-base oils have been reported, but the petroleum obtained from the wells so far drilled has revealed on analysis an asphalt base. So too, though reports of light-gravity oils have been published, the oils actually extracted in recent years have ranged from 0·928 to 1·02 specific gravity. Not more than 3% of petrol or 7% of kerosene has been obtained from Venezuelan petroleum in refinery practice.

The commercial production of petroleum in Venezuela began in 1917. The accompanying table gives the production, the amount refined, and the exports of crude oil.

	Production		Refined at San Lorenzo		Exports to Curaçao	
	Metric Tons	Barrels	Metric Tons	Barrels	Metric Tons	Barrels
1917 ...	18,255	119,734	8,871	58,185	9,383	61,541
1918 ..	50,710	332,607	24,648	161,666	25,298	172,489
1919 ..	64,628	423,895	54,000	354,000	10,600	60,522

No phenomenal yields of petroleum have been obtained from any of the seven wells that were in active

production in 1919. The highest known output of the Zumbador well, in the Mene Grande field, was 229 86 barrels per day. Commercial production in Venezuela has been attained only by the Caribbean Petroleum Co. A Venezuelan company, under a title granted Sept. 3, 1878, produced and sold locally for many years small quantities of kerosene refined by crude methods from oil won in shallow wells in the municipality of Rubio, District of Junin, State of Táchira, but little is known of its activities, which have been conducted on a small scale. Its production from 1905 to 1907 averaged 50 metric tons a year. No later statistics of its output are at hand.

Map of Venezuela.

The production of asphalt in Venezuela by companies in recent years is as follows:

		1917 Metric Tons	1918 Metric Tons	1919 Metric Tons
New York & Bermudez Co.	Guanoco	52,991	46,453	45,932
South American Company	State of Zulia	72	50	—
Cia. Anonima Minerales Petroliferos Riopauji	State of Trujillo	1,009	—	—
	Totals	54,072	46,503	45,932

At first the larger part of the Venezuelan crude oil was shipped in barges to the Royal Dutch refinery on the Island of Curaçao, but in 1919 the plant at San Lorenzo took over four-fifths of the output of the Mene Grande wells. The San Lorenzo refinery is designed to supply only the Venezuelan trade. Exports to the foreign markets are made from Curaçao refinery.

Various estimates have been made of the reserves of petroleum in Venezuela. These range from 150,000,000 to 250,000,000 metric tons, based on estimates of the probable oil-bearing territory and the richness of the oil sands. These estimates will undoubtedly have to be reduced in the light of the experiences of the producing companies. Of the 1,028 areas of 500 hectares each, selected by the Caribbean Petroleum Co. in 1913 for exploration and possible development, 767 areas had been renounced to the Venezuelan government by December 31, 1919, after examination or drilling. It was expected that more would be renounced in 1920 after detailed geologic examinations. On this basis the estimated reserves of available petroleum may have to be reduced to 40,000,000 or 60,000,000 metric tons Altogether, Venezuela has not lived up to expectations

No estimates are available as to reserves of asphalt. The deposits of Bermudez Lake give evidence of constant renewal, and other asphalt lakes exist also, both in the east and in the west, which, however, have not been commercially developed.

The only active producer of petroleum in Venezuela previous to 1919 was the Caribbean Petroleum Co., of Camden, New Jersey. The company, after a thorough exploration by a party of thirty-five geologists, headed by Ralph Arnold, selected in 1913, for preliminary work of development, 1,028 areas of 500 hectares each, situated on both sides of Lake Maracaibo. The principal holdings of the Caribbean Petroleum Co. are in the Mene Grande field, seventy miles east of Maracaibo and sixteen miles inland from San Lorenzo; in the Miranda district, east of Lake Maracaibo; at Perijá, fifty miles west of the city of Maracaibo; and in the Santa Cruz de Mara district. Drilling in the Mene Grande field began in January, 1914. The first well drilled struck oil at a depth of 390 ft. and produced about 10 barrels a day. In the next two years, five other wells were sunk ranging from 600 to 1,700 ft. in depth. Oil was found in all; most of the wells had to be capped. The following statement shows the condition of the productive wells in the Mene Grande field in the fall of 1920:

Well	Drld.	Ft.	Initial Production Metric Tons	Present Conditions
Zumacaya No. 1 ...	1915	583	40	Capped
Zumaque No. 1 ...	1914	390	40	Capped
Zumaya No. 1 ...	1914	1,667	400	Producing
Zumba No. 1 ...	1915	882	250	Choked with sand
Zumbador No. 1 ...	1915	869	300	Producing
Zumbel No. 1	1915	552	400	Choked with sand
Zo. No. 1 .	1918	797	40	Dammed with cement to exclude water
Zumaque No. 2 ...	1919	903	100	Dammed with clay and cement to exclude water

The output by wells in this field has been as follows:

	1917 Metric Tons	1918 Metric Tons	1919 Metric Tons	Jan.-June, 1920 Metric Tons
Zumbador No. 1	10,240	26,103	36,862	23,102
Zumba No. 1	8,015	11,548	6,592	4,522
Zumbel No 1			336	652
Zumaque No. 2			102	15
Zumacaya No. 1	—		528	76
Zumaya No 1			19,068	842
Zo. No. 1	—	3,059	1,141	76
Totals ...	18,255	50,710	64,628	29,285

Work was started by this company in 1917 in the Santa Isabel field in the district of Miranda, State of Zulia, and drilling was continued throughout 1920. In the Perijá field the first well of the Caribbean Petroleum Co., drilled in 1915, showed oil in considerable quantities at 1,227 ft., and was shut in. Two more wells started in 1916 were completed in 1917 and 1918 respectively, without satisfactory results. In 1919 one well was drilled to a depth of 2,235 ft. without success. This final failure induced the company to renounce many of its holdings in the Perijá field. Development of the Mara fields was begun in 1917. Three wells were drilled in 1917 near Iniciarte, to depths respectively of 900 ft., 811 ft., and 2,018 ft. Shows of oil were obtained, but not in commercial quantity. When a well begun

in May, 1918, was carried to 1,980 ft. without a commercial yield of oil, the company renounced its concession to a number of areas in this field. Three wells in the Cachirí field were drilled in 1917 down to basalt, to depths of 1,950 ft., 430 ft., and 736 ft. respectively. No commercial quantities of oil were found. A well drilled in 1918 encountered igneous rock at 745 ft., and was abandoned. In the La Sierrita field, in the district of Mara, a well was started in October, 1919. Despite delay occasioned by a lack of water, requiring the laying of a pipe-line to the Ciénega de Sinamaica, twelve miles distant, the well had been carried by the end of the year to 1,146 ft. through clay, shale, and sand. Drilling was continued during 1920.

The Venezuelan Oil Concessions, Ltd., of London, holds a concession covering 8,128 acres in the district of Maracaibo, on the west side of the lake, and in the district of Bolívar, on the east side of the lake. Development of the Bolívar area began late in 1913, with the drilling of wells at La Rosa and Santa Rita. The Santa Rita well was drilled to a depth of 1,600 ft. without striking oil, and was then abandoned. In the La Roca well, oil sand was met at a depth of 800 ft.; and at a depth of 1,500 ft. a sand giving oil of 30° B. was struck. A great quantity was given at first; but after ten days the output had decreased to 10 barrels a day. No attempt was made to pump the well, which was abandoned. The company fought a losing fight with the mosquitos, which decimated its workers with malarial diseases. The drilling system originally adopted proved unsatisfactory, and new equipment was ordered in the United States. The outbreak of the War prevented the delivery of this equipment. Nevertheless in the next three years five more wells were drilled, ranging in depth from 600 ft. to 1,800 ft., and spread over a wide area. Oil is said to have been found in five of the seven wells, of which those near Santa Barbara are believed to be of commercial value. Drilling in the Barroso field was started in June, 1918; but the well was discontinued after an accident to the casing. A second well begun in the latter half of that year was abandoned at 536 ft. In the spring of 1920 there was practically no activity in the Bolívar holdings of the Venezuelan Oil Concessions, Ltd.

The principal holdings of the Colon Development Co., of London, are in the Colon district, State of Zulia, especially in the vicinity of El Cubo, near the Colombian border, 100 miles south-west of Encontrados, and are contiguous to the Barco concession in the State of Santander del Norte, Colombia. The geologic exploration and the subsequent development of the Colon field were considerably hindered by the depredations of the Motilones Indians, necessitating an armed guard about the field camps and drilling machinery day and night. Drilling began early in 1914. The first well was abandoned at a depth of 700 ft. The second well, on the Rio Oro, reached over 1,000 ft., giving an initial output of 200 barrels a day of light-gravity oil. Three wells were drilled along the Rio Tarra, the deepest to 2,362 ft. A sixth well was carried to 328 ft. during 1919. The Colon Development Co. had drilled up to May 1, 1920, six wells, as described. Three of these were found productive and capped.

The British Controlled Oilfields, Ltd., is operating the Buchivacoa concession of 3,000 square miles in the State of Falcón, acquired from the Venezuelan-Falcón Oil Syndicate, Ltd. The property is said to contain a sharp, narrow anticline traceable for fifty miles from north-east to south-west. Toward the west, the anticline pitches south-west and shows recurring dome structures. Seepages of a light oil are numerous. Development is taking place in two main divisions. In the western division, of which the field headquarters are at Altagracia, two wells have been drilled. Both the rotary and the cable systems of drilling have been used. The first well gave a small quantity of oil at a depth of 1,800 ft.; the second showed oil at a depth of 1,000 ft. Oil, when met in commercial quantities, will be transported by a pipe-line to be built to Altagracia or to the Caribbean coast, fifty miles to the north. The field headquarters of the eastern division are at Dabajuro, eight miles south of the Caribbean coast; and the drilling camp is twenty-four miles to the south-east. Three standard drill rigs were under construction at the end of August, 1920.

The following American companies are developing in the Maracaibo district: The Maracaibo Oil Exploration Co., of New York, organized in 1919; the Sun Co., of Philadelphia; the Venezuelan Oilfields, Ltd., organized under the laws of the State of Delaware. One English company, the North Venezuelan Petroleum Co., Ltd., began exploration in September, 1920, the principal deposits lying in the vicinity of Píritu.

The petroleum activities described in the foregoing paragraphs are all in the Maracaibo basin. It remains to mention the work done in the Paria district. This district comprises the coastal belt of the Gulf of Paria from the northern part of the Orinoco delta to the peninsula of Paria, an area roughly seventy miles long and thirty miles wide. To this may be added the coastal belt and outlying islands from the peninsula of Paria as far west as Barcelona, where oil seepages occur in local areas. The oldest rocks exposed in the Paria district are the pre-Cambrian gneisses and schists which form the backbone of the peninsula of Paria. In the metamorphosed sediments which accompany these a few Ordovician fossils have been found; but in general the oldest determinable rocks of this district are Cretaceous.

The most striking evidence of the occurrence of petroliferous formations in eastern Venezuela is the famous Bermudez asphalt lake, situated near the town of Guanoco, three miles above the confluence of the Guanoco and San Juan rivers. The lake is twenty-five miles from the Gulf of Paria and 105 miles due west of the equally renowned Pitch Lake on the island of Trinidad. The Bermudez Lake is formed by the overflow of several oil springs on a swamp. It is about 1,110 acres in extent, and varies from 1·9 ft. in thinner parts to 20 ft. in thickness near the seeps. The lake is believed to consist of the residues of an asphalt-base petroleum, the lighter oils having been distilled away. The flows are composed of alternate layers of asphalt and fine sand. Crusts of slag and burned asphalt point to fires caused by Indians or by the natural ignition of gases emanating from the lake. The lake is overgrown by jungle and covered with water. Blowholes of gas occasionally occur. Water accompanies them, frequently rather warm and highly impregnated with sulphuric acid. The asphalt of the lake shows upon analysis 64·39% of bitumen soluble in carbon disulphide, 30% of water, 2·08% of inorganic matter, and 3·53% of organic matter. After extracting the water the remainder gives 96% of bitumen and 2 to 5% of earthy matter, with a loss of 2%. The lake is owned and exploited by the New York & Bermudez Co., a subsidiary of the General Asphalt Co. of Philadelphia, which is also owner of the Pitch Lake of Trinidad. In extracting the asphalt, a dam of slag and waste is built to exclude water, and the water within the enclosed area pumped out. The asphalt is dug out by hand and loaded into cars. These are hauled by cable to the light railroad, which conveys it eight miles to Guanoco. A refinery with a capacity of fifty metric tons a day expels the water. The refined pro-

duct is then ready to be exported. The United States takes practically all of the shipments of Bermudez asphalt, except occasional small exports to Trinidad.

A second pitch lake occurs in the Pedernales field, at La Brea, on the north-west coast of the island of Capuré. The lake is half a mile in length and 100 to 200 yards across. It is fed by several active oil springs and one asphalt cone. About three-fourths of a mile south of the main deposit are two small cones; additional deposits occur two miles to the north-east. Asphalt deposits are also found on the island of Plata. The Pedernales asphalt deposits were exploited by a German firm for a short time in 1902. The ruins of the German refinery are still visible one mile from Pedernales. Mud volcanoes are reported near Bermudez Lake and the neighbourhood of Maturín.

The New York & Bermudez Co. began drilling for oil in 1913. Wells had been drilled on all areas by June of that year. The lands on the peninsula of Paria were soon decided to be not commercially valuable, and were abandoned. Seven wells, ranging from 200 to 1,100 ft. in depth, were drilled on Pedernales Island. Difficulties with heaving sands, soft mud, and gas pressure necessitated several changes in the method of drilling. Traces of oil were found, but none in commercial quantity. Several wells were sunk in the Guanoco area, near Bermudez Lake, ranging in depth from 200 to 4,200 ft. In some a heavy oil of 1·020 specific gravity, almost an asphalt, was found. Such an oil would have to be heated in order to be pumped. No oil of commercial value was obtained. Much geological investigation has been done to find the oil, which is believed to exist here in large quantities.

The Caribbean Petroleum Co., of Philadelphia, has been drilling in the Chapapotal field, fourteen miles north-west of Maturín, in the State of Monagas, near Chaguaramal, and in the Guanipa field. The field headquarters of the company are at Guanoco. Two wells were drilled in 1918 in the Chapapotal field. The first was abandoned at a depth of 208 ft. after an accident. The second was carried to a depth of 3,231 ft. Asphalt was encountered but no fluid oil in commercial quantity. The exploration work was nearly completed at the end of 1919, with results that do not appear to indicate a commercial value for the deposits. Further exploration work will probably be undertaken.

The Petroleums of Borneo.—At the meeting of the Institution of Petroleum Technologists held on March 15, James Kewley read a paper describing the characteristics of the petroleums obtained in Borneo.

The petroleum industry of the East Indies is of comparatively recent growth, dating back in the case of Borneo to not earlier than 1897. The production of the Koetei fields, which were first developed, has steadily increased and has been supplemented by that of areas developed at later dates. Indications of petroleum had long been known in Borneo and the other islands of the East Indian archipelago. As far back as 1853 Motley noticed oil occurrences in the island of Labuan. In 1863 Menten found also seepages in the island of Tarakan, on the east coast. In 1866 a shallow well was drilled in Labuan which gave a small flow of oil for thirteen years at least. Collingwood, in 1868, described a petroleum spring in British North Borneo, and stated that others were known. About 1887 three wells were in existence on the Klias peninsula on the north of Brunei Bay, and these gave oil in very small quantities. Menten, in 1888, obtained oil and coal concessions near the mouth of the Mahakam River, which concessions give to day the most important output. In 1891 he obtained further concessions near Balik Papan, then a tiny fishing village, now a thriving refinery centre. Further indications are found in the Bolongan area in West Borneo, Sarawak, and elsewhere. In 1897 the first well was put down at Sanga Sanga, and oil was found at 58 metres In August, 1898, the Nederlandsch Indische Industrie en Handel Maatschappij, and about the same period several other companies, for instance, the Bombay-Burmah Trading Co. in British Borneo, and the Koetei Exploration Co. in East Borneo, began operations. In 1901 the Royal Dutch began to drill in Koetei, and the East Borneo Co. a little later. The production of these fields rapidly increased, and had already reached a figure of nearly 60,000 tons in 1900. At the present day the production of Borneo is about 4,000 tons per day.

There are at present three important producing areas in Borneo: (1) the Koetei area, extending from the mouth of the Mahakam River southwards toward Balik Papan Bay; (2) the Tarakan field, situated on the island of Tarakan on the east coast, about 80 miles south of the British North Borneo frontier; (3) the Miri area, on the west coast in Sarawak, about 150 miles south of Brunei Bay. These three areas differ to some extent geologically, and considerably in respect to the types of oil they yield

The oil-bearing rocks of the Koetei area are of Pliocene and Miocene age. They consist of Pliocene sands, gravels, and clays laid down under delta conditions, the sands being dominant and the clays subordinate. Lignites containing a high water content (25%) are of frequent occurrence, as is the case in the Tarakan area also. Boulders of coal of lower water content from the lower Koetei formation also occur. This series lies unconformably on the Miocene, which is made up of interbedded clays and sands, with frequent coal beds lenticular in form, all laid down under delta conditions. Below these strata is found the greensand formation, which consists of glauconite sands with interbedded foraminifera limestones, the age of which has not yet been definitely determined, but which are probably early Miocene. Below these, again, a marl which is probably of Eocene age, similar to that found in North Borneo. The Miocene and Pliocene were laid down under delta conditions, the material having been brought down by large rivers such as the existing Mahakam, which flowed down from the central massif of Borneo. This massif, which is exposed in the south-west of Borneo, and which almost certainly extends under the surface strata through the centre of the island, is of igneous rock. On its flanks the Miocene and Pliocene deposits were laid down. Subsequent lateral pressure in a north-west to south-east direction gave rise to a series of folds in this area running north-east to south-west, roughly parallel to the Macassar Straits. These folds appear as the well-marked anticlines of Sanga Sanga and Palarang. The general folding process must have begun before the Pliocene rocks with lignites were completely laid down, so that the tops of the folds evidently appeared as islands in the Pliocene sea, and on being denuded supplied in part the material which was deposited in the tectonic troughs. The sinking of these troughs and the filling in of the same must have taken place at about the same rate, as indicated by the uniformity of the strata traversed by the wells in the Tarakan field. A further subsidiary folding was caused by lateral pressure in a north-east and south-west direction, which, however, was not so marked, so that the anticlines appear as very elongated domes. On these elongated domes the oilfields were developed.

In the Koetei fields three distinct types of crude oil are found, namely, heavy asphalt oils in the upper strata,

light asphalt oils at greater depths, and paraffin wax oils at still greater depths.

The structure of the Tarakan field is that of a system of two domes with a depression in between, the major axes of which run in a north-south direction. In this area, which is also of delta formation, Pliocene sand predominates. The field is developed in part of the delta which was nearer the coast and where consequently sands predominate, the interlying clays being not so well marked. Pliocene coals, or rather lignites, often containing boulders of older coal from the late Miocene formation, are frequent. The oil from this field is markedly uniform in composition.

The Miri field lies on the west coast of Borneo. The geological structure here is not yet so well known as that of the two fields described above. There is a well-marked anticline, the eastern wing being very much the steeper. The oil is drawn from the western wing. The strata here are also of Miocene age, and coals are absent. The oils of the Miri field are fairly uniform in character, but differ fundamentally from those of the Koetei and Tarakan fields.

The crude oils of Koetei fall into three main classes: (*a*) heavy asphalt-base crude oils; (*b*) light asphalt-base crude oils; (*c*) light paraffin-base crude oils. The oils have one character which sharply differentiates them from practically all other crudes so far known. The specific gravities of the distillates are much higher than those of corresponding distillates from most other crudes. The same applies to the refractive indices. These characters, and the inability of kerosenes produced from these crudes to burn in any ordinary lamp without arrangements for an extra supply of air, were naturally soon discovered (Ragosin, *Pet. Rev.*, vol. 8, 1903, p. 59). The reason for this is the presence of unusually large proportions of aromatic hydrocarbons in these oils. The occurrence of aromatic hydrocarbons in crude oils has long been known. In fact, aromatic hydrocarbons have been found in small quantities in most crude oils, but seldom to an extent greater than 15%, usually to a much less extent. Examinations of Koetei oils have shown that they contain extraordinary quantities of aromatic hydrocarbons, amounting to as much as 40% consisting chiefly of benzine, toluene, and meta-xylene.

It is interesting to note that the high aromatic content of Koetei oils, which some years ago rendered them of comparatively low value, eventually rendered these oils of the greatest importance to the British Empire as a source of toluene.

The consideration of a few generalizations drawn from a study of the occurrence and characters of the crude oils of Borneo, particularly of the Koetei field, may be found to throw a little light on the origin of petroleum. The crude oils of the Koetei field were either developed in situ or else they migrated from some mother rock into their present reservoirs. If these oils were found in situ, then they must be of vegetable origin, as there is no indication in the sands and coals of sufficient animal matter to have yielded such quantities of oil. Further, had they developed in situ, they must have arisen either from the coal or from the vegetable matter which formed the coal. Experience does not lead one to expect that they have been formed from the coal, and the change of vegetation, partly into coal, partly into oil, is equally contrary to experience. The other view, that the oils migrated into their present position, is much more probable, and is supported by certain evidence afforded by the differences in composition of the crude oil from different horizons. Conditions advantageous to migration exist in the Koetei and Tarakan fields. In the former, clays and sands alternate, but the layers are discontinuous owing to their formation under delta conditions, so that a zigzag course is open to the oil migrating upwards, there being, however, many opportunities for retaining portions of the oil under impervious clays *en route*. A possible source of the oil is to be found in the foraminifera limestone (which is a shallow water deposit accumulated quickly) of the early Miocene, or possibly in the marl formation of the underlying Eocene. It is possible that as the oil migrated upwards, coming into contact with or passing through the coal beds, some chemical interaction between the oil and the coal may have taken place. One might expect, therefore, differences in composition of the oils which have been arrested in their upward course by local obstacles at different horizons. This is, indeed, undoubtedly the case. The oil found at the greatest depths so far drilled is rich in paraffin wax. The oils found at higher levels are poorer in paraffin and richer in aromatic and asphaltic constituents. The early Miocene greensand formation, which underlies the Koetei petroliferous formations, has not yet been penetrated by borings, but it is found outcropping in the Palarang anticline, which runs parallel to that of Sanga Sanga, some miles further inland. The nature of the oil found there in these lower strata is in accordance with the view put forward. This oil had the relatively low specific gravity of 0·831, yielded 40% of a kerosene of specific gravity 0·809, which burnt well in a Hinks lamp, and which was of very low aromatic content. The crude was, moreover, rich in paraffin wax. This oil comes from a level below the coal-bearing strata. These facts suggest the possibility of the paraffin-rich and aromatic-poor oil having undergone some chemical interaction with the coal in its passage upwards, which resulted in a diminution of the wax content and increase in the aromatic and asphaltic constituents. It is difficult to understand in what way such a change could have come about. The facts, however, exist and need some such explanation. In the Miri fields, where coals are absent, the oil is low in aromatic and asphaltic content; the oils of Perlak, in Sumatra, where coals are absent, are lower in aromatic and asphaltic content than those of Moera Enim, in which field coals are present. The fact also that the difference in character with increase of depth is so very much less marked in the Tarakan field, where the geological conditions are much more favourable for easy migration, lends support to this idea.

Flotation of Cassiterite.—Patent No 28,999 of 1919 (159,025) granted to M. T. Taylor and J. W. Partington describes the process for concentration of tin ores by flotation as developed at East Pool mine, Cornwall. Herewith is given the specification.

The present invention is based upon the observation that sulphonated fatty or resin acids have a favourable effect in promoting the separation of certain metal compounds, for instance, the compounds of tin and tungsten such as the oxides of the metals referred to and scheelite occurring in ores. In accordance with the invention, products obtained by treating fatty or resin acids with sulphuric acid are employed. The fatty acids whose sulphonated derivatives are employed in accordance with the invention are the higher fatty acids such as are present in oils and fats, and the resin acids are ordinarily those derived from colophony. The fatty acids obtained for instance by treating soap or a solution of soap with a weak acid medium to effect the separation of the fatty acids, or soap itself may be treated with strong sulphuric acid, during which treatment it will be found that sulphur dioxide is liberated. The waxy product obtained, which is usually of a blackish or dark colour, separated from the aqueous layer formed in the treatment, and optionally also from any crystalline

matter separating from the aqueous layer, may be employed in the flotation process.

In the treatment of soap with strong sulphuric acid in the manner indicated, it would appear that derivatives as, for instance, sulphonated products or derivatives of certain fatty and/or resin acids contained in the soap are formed. The sulphonated fatty or resin acids may be employed in the form of a solution in, or otherwise in association with, agents which in themselves may act in the direction of facilitating the separation of the metallic values in consequence of their selective action for certain minerals or of their emulsifying or froth-forming properties. Thus the sulphonated fatty or resin acids may be dissolved in or employed in association with esters of fatty acids as, for instance, propyl, butyl, or amyl acetates, and/or with cyclic compounds containing nitrogen in the ring as, for instance, pyridine or like compounds, or commercial products containing these bodies, and the solution thus produced may be associated with phenolic bodies such as phenol itself or eucalyptus oil or other oily bodies hitherto employed in flotation processes.

The flotation of tin, tin oxide, wolfram, and scheelite can be effected by the employment of flotation agents in accordance with the invention, and it has been found by the inventor that by the employment of equal parts by weight of the fatty acids of palm oil and strong sulphuric acid in forming a sulphonated product, which is employed together with pyridine and amyl acetate in the manner above indicated, particularly good results may be obtained in the separation of these minerals from the gangue and other matters with which they are normally associated in the form of ores or concentrates.

The following particulars are given, by way of example, for the purpose of illustrating a suitable manner of carrying the invention into effect: Soap or the fatty acids set free by the treatment of soap with weak acids as, for instance, sulphuric acid of 10% strength, or by means of acetic acid, are treated with strong sulphuric acid of, for instance, 95% strength, and the product which floats on the aqueous layer is further treated with, for instance, pyridine or amyl acetate, or both pyridine and amyl acetate, after separation from or while in contact with said layer, so that the product is dissolved by the pyridine or amyl acetate, or forms compounds therewith. From what has been stated above it will be understood that instead of pyridine other cyclic compounds containing nitrogen in the ring may be employed, and that instead of amyl acetate other fatty acid esters may be used. The fatty acids of palm oil are treated with an equal weight of concentrated sulphuric acid with or without the aid of heat. Sulphur dioxide is evolved and the resulting product is usually dark in colour. When the reaction has ceased, the product floating upon the aqueous layer is separated either by decantation or by allowing the reaction mixture to cool and separating the solid reaction product. The reaction product, which is more or less solid at ordinary temperatures, is then masticated or kneaded or boiled with water to remove the free mineral acid with which it may be associated.

The product thus obtained may be added in the solid state to the material as, for instance, by introducing it into the flotation apparatus in which it will be converted into an emulsion with the water, or it may be previously emulsified with water or dissolved in any suitable solvent as, for instance, pyridine or like nitrogen-containing cyclic compounds, or propyl, butyl, or amyl acetate, or the corresponding alcohols, and the emulsion or solution may be then added to the material to be subjected to the flotation treatment. The ore or mineral-bearing material is crushed to pulp of a suitable degree of fineness either by wet or dry crushing, and is then conveyed to a flotation apparatus where the said pulp is agitated with water, and in the course of this agitation a small portion of the flotation agent according to the invention is added to it. This flotation agent attaches itself preferentially to the mineral particles in the ore and leaves the gangue or waste substantially unaffected. Air in minute sub-division is introduced into the aqueous pulp and attaches itself to the reagent-coated mineral particles, thus carrying them to the surface in the form of a froth or scum, which is collected, and the mineral separated therefrom by settling or other suitable means.

Arizona Copper Company's Metallurgy.—In the *Engineering and Mining Journal* for February 5, J. O. Ambler writes on the method of saving gold and silver at the Arizona Copper Company's smelting plant. The average gold content of the blister copper per ton is 3 dwt., and the silver content averages 5 oz. per ton. This precious metal could not be recovered profitably by electrolytic refining, so experiments were made in the converter with the object of reproducing the old Welsh method of collecting gold and silver in the bottoms. The results were sufficiently encouraging, and the author gives a description of the practice eventually adopted. A charge consisting of about fifty tons of matte and the necessary silicious ore and cleanings is blown in 12 ft. Great Falls-type converters to the white-metal stage as usual. The white metal is then blown until part of it is converted into copper, this blowing time being dependent on the amount of white metal in the charge, the percentage of enriched product desired, and the other operating factors. The converter is then turned down, and the overlying white metal is poured off into a ladle. The copper remaining in the converter, which still contains a small amount of white metal and is enriched in gold and silver, is finished and poured as usual, this operation taking from three to five minutes, depending on how clean a separation has been made. The white metal which was poured off into the ladle is then poured into the same converter and finished, the copper produced being impoverished in gold and silver. The principal difficulties encountered in operation are to control the percentage of copper produced as "enriched," and to obtain a clean separation when skimming the white metal from the enriched product. As a result of experience, the operators at the plant can now estimate the percentage of enriched product with a fair degree of accuracy, but the results obtained are still entirely empirical. With a charge containing about fourteen tons of copper, the blowing time to produce 55% of enriched product from the white-metal stage averages from fifty to fifty-five minutes under the conditions prevailing in this plant, but this varies with the size of the charge, cleanness of the skim, temperature of the charge, amount of cold scrap fed, temperature of the blast, and other conditions, and is still largely a matter of good judgment based on experience. The foremen in charge have developed a scheme for separating the copper and white metal, by observation of the appearance of the molten stream on a rabble blade, which is entirely satisfactory.

SHORT NOTICES.

Subsidences and their Prevention.—At the March meeting of the South Wales Institute of Engineers, R. C. Morgan read a paper on the causes of subsidences in coal mines and the best safeguards for their prevention.

Compressed Air in Mines.—The *Colliery Guardian* for March 4 contains a report of a discussion at Wigan Mining College on the relative suitabilities of compressed-air power and electric power in mines.

Flotation of Coal.—A paper by E. Bury, W. Broadbridge, and A. Hutchinson on the application of froth flotation to the purification of coal is published in the Transactions of the Institution of Mining Engineers.

Monel Metal.—In *Chemical and Metallurgical Engineering* for February 16, Paul D. Merica writes on the physical characteristics of monel metal, the alloy of copper and nickel.

Nickel Alloys.—In *Chemical and Metallurgical Engineering* for March 2, Paul D. Merica, of the research department of the International Nickel Co., writes on nickel steels and iron alloys high in nickel.

Chloridizing-Roasting of Copper Ores.—In the *Engineering and Mining Journal* of March 5, N. Ostman describes the Ramen-Beskow furnaces used in extracting copper from burnt pyrites by roasting with salt and subsequent leaching. These furnaces and the chemical considerations connected therewith were described in the MAGAZINE for December, 1918.

Electric Iron Smelting.—In *Chemical and Metallurgical Engineering* for March 9, Gerard de Geer writes on electric smelting of pig iron at Domnarfvet, Sweden.

Cobalt Brasses. — *Chemical and Metallurgical Engineering* for March 9 publishes a translation of a paper by Leon Guillet, which appeared in a recent issue of *Revue de Metallurgie*, on cobalt brasses.

Copper Assay.—In the *Engineering and Mining Journal* for March 19, G. J. Hough describes a modification of the Fleitmann method of copper assay.

Mount Quamby, Queensland.—The *Queensland Government Mining Journal* for January contains a paper by Lionel C. Ball on the Mount Quamby gold deposits between Cloncurry and Mount Cuthbert.

Cobalt in Queensland.—The *Queensland Government Mining Journal* for January publishes a paper by J. H. Reid on the deposit of cobalt near Selwyn, in the Cloncurry district. Note of this deposit was made in the MAGAZINE for November last.

Gold and Platinum in Chile.—In the *Engineering and Mining Journal* for March 19, F. Mella describes alluvial deposits containing gold and platinum on the island of Chiloe off the coast of southern Chile.

Spanish Pyrites.—In the *Mining and Scientific Press* for January 22, Courtenay De Kalb writes on the pyrites industry of South Spain. In the issue of February 5 he describes the methods of extracting the copper.

Pyrites in Coal.—At the meeting of the Manchester Geological and Mining Society held on March 8, James Lomax read a paper on the various forms of pyrites in coal, their probable origin, and their effects on being exposed to atmospheric influences.

Nevada Consolidated.—In the *Mining and Scientific Press* for March 5, A. B. Parsons commences an article giving a historical account of the Nevada Consolidated Copper Company.

Gold Mining in Nicaragua.—In the *Mining and Scientific Press* for March 12, Robert Hawxhurst, Jr., describes the Piz Piz gold-mining district, Nicaragua.

British Aluminium Water Power.—The *Engineer* for March 4 contains an illustrated article describing the new scheme for providing additional electric current for the British Aluminium Company's smelting works near Fort William, Scotland, by utilizing the waters of Lochs Trieg and Laggan and of adjoining rivers.

Borneo Petroleum.—In the *Engineering and Mining Journal* for March 5, W. H. Emmons and J. W. Gruner write on the Sanga Sanga oilfield in the Koetei district, Borneo.

Mexican Oil.—In the *Engineering and Mining Journal* for March 19, A. H. Redfield discusses the oil resources of the states on the isthmus in Mexico, Vera Cruz, Oaxaca, and Chiapas.

Conditions in China.—*Mining and Metallurgy* (New York) for March contains a paper by H. Foster Bain entitled: "Problems Fundamental to Mining Enterprise in the Far East."

RECENT PATENTS PUBLISHED.

☞ *A copy of the specification of any of the patents mentioned in this column can be obtained by sending 1s. to the Patent Office, Southampton Buildings, Chancery Lane, London, W C.2., with a note of the number and year of the patent.*

19,027 of 1919 (158,288). J. G. MACLEOD, London, and W. J. BROWNING, Rio Tinto. Obtaining sulphuretted hydrogen from sulphurous gases obtained by the roasting of sulphides, by passing these gases continuously through a carbonaceous zone maintained incandescent by its own combustion.

21,220 of 1919 (158,293). A. MATHESON, London. Method of producing soluble phosphate from alunite.

22,056 of 1919 (158,294). S. E. MUNOZ, Lorenzo Marquez, and S. SERUYA, Johannesburg. Cushioning devices for hand hammer-drills.

23,318 of 1919 (158,926). A. J. and H. D. EVANS, London. Improved method of recovering tin from tin-pot skimmings.

24,766 of 1919 (159,244). C. M. CONDER and G. T. TWYNAM, Camborne. Improved crusher of the roller and ring type.

25,056 of 1919 (158,937). W. GALLAGHER, Johannesburg. Instrument for surveying bore-holes.

26,470 of 1919 (134,536). MASUMI CHIKASHIGE and DENZO UNO, Kyoto, Japan. Extracting selenium and other metals from the slimes of electrolytic refining plant.

27,951 of 1919 (158,708). A. H. JONES, Tonopah, Nevada. Flotation machine.

28,355 of 1919 (158,992). A. A. KELLY and B. D. JONES, London. Method of preparing alkali pentaborates from boronatrocalcite or other boron minerals.

28,546 of 1919 (159,008). J. E. HURST, Mansfield, and E. B. BALL, Troon. Aluminium alloy suitable for internal combustion engines containing 0·5 to 6% of chromium.

28,763 of 1919 (159,280). W. B. BALLANTYNE, London. Method of introducing chromium or other refractory metal into steel.

28,832 of 1919 (159,285). E. EDSER, H. L. SULMAN, and F. B. JONES, London. Improvements in process for floating coal, based on W. Russell's process described in Patent No. 122,454.

29,031 of 1919 (158,740). W. P. HESKETT, Wanganui, New Zealand. Method of producing fine metallic powders.

29,283 of 1919 (159,314). W. W. RICHARDSON, London. Improvements in the inventor's revolving classifier and concentrator.

29,303 of 1919 (147,530). NEW JERSEY ZINC Co., New York. Improvements in the Wetherill process for making zinc, lead, and other oxides.

29,359 of 1919 (159,318). R. H. BICKNELL, London. Tunnelling machine.

30,340 of 1919 (159,342). D. WHITAKER, Leicester. Tunnelling machine.

30,951 of 1919 (159,071). J. J. COLLINS, Winsford, Cheshire. Method of extracting tin from ores by treatment with dry chlorine gas. This process was described in the MAGAZINE for November, 1920.

31,814 of 1919 (159,380). R. STOREN, Kongsberg, and R. JOHANSON, Odda, Norway. In magnetic

separation, a method of rendering pyrrhotite permanently non magnetic so that weakly magnetic iron oxides can be separated from it.

1,712 of 1920 (159,086). S. E. SIEURIN, Hoganas, Sweden. Method of producing alumina from aluminium chloride formed by treating aluminium ores in hydrochloric acid.

5,510 of 1920 (154,167). F. COURTOY, Brussels. Coal washer

6,092 of 1920 (139,523). SIEMENS-SCHUCKERTWERKE, Berlin. Rotary rock-drill.

6,912 of 1920 (140,069). SCHIELE & BRUCKSALER, Hornberg, Baden. Increasing the resistance of aluminium to acid and alkaline liquids.

8,213 of 1920 (159,102). GENERAL ELECTRIC Co., Schenectady, New York. Producing a coating of chromium-iron alloy on surfaces of iron and steel.

11,326 of 1920 (142,129). J. CHOPPINET, G. GILLON, and V. DEFAYS, Brussels. An apparatus for determining the deviations of bore-holes, comprising a rocking beam suspended above a disc having uniform rotary motion, which moves laterally in accordance with the deviations of the bore-hole, the rocking beam carrying devices arranged in the apices of a regular polygon that is concentric to the rocking beam, said devices being arranged to come into contact with a radius of the rotating disc at intervals of time varying with the relative positions of the disc and the rocking beam, and the recording of which allows of determining the distances between the centre of the disc and the axis of the rocking beam, that is to say, the displacement of the disc and consequently the deviations of the bore-hole and the horizontal direction of said deviations.

12,941 of 1920 (143,218). WENDEL & CIE, Paris. Blasting cartridges using liquid air.

12,959 of 1920 (152,300). FULLER-LEHIGH CO., and A. G. KINYON, Fullerton, Pennsylvania. To assist the conveying of coal dust by pressure, the introduction of small amounts of air into the bottom of the conduits, thus making the dust fluent.

NEW BOOKS, PAMPHLETS, Etc.

☛ Copies of the books, etc., mentioned below can be obtained through the Technical Bookshop of *The Mining Magazine*, 724, Salisbury House, London Wall, E.C.2.

American Petroleum Register. Price $10·00. New York: *Oil Trade Journal*, 120, Broadway.

The Recovery of Nitrate from Chilean Caliche. By A. W. ALLEN. Cloth, octavo, 50 pages. Price 6s. net. The author first describes the standard Shanks process for extracting nitrate, and then proceeds to deal with his own process, for which patents are pending.

Year-Book of the Scientific and Learned Societies. Cloth, octavo, 360 pages. London: Charles Griffin & Co., Ltd. This is the 37th annual issue of a most useful handbook giving details of the various scientific and technical societies, with records of the papers and transactions during the year.

Phosphate in Canada. By HUGH S. SPENCE. Published by the Canadian Department of Mines.

Geology of the Plateau Tin Fields. By J. D. FALCONER. Published by the Geological Survey of Nigeria.

Lead Ores. By T. C. F. HALL. Paper covers, 135 pages. Price 6s. net. Published for the Imperial Institute by John Murray.

Handbook of Metallurgy, Vol. 1. By CARL SCHNABEL, translated by HENRY LOUIS. Cloth, octavo, 1,180 pages, illustrated. Price 40s net. London: Macmillan & Co., Ltd. This is the third edition of this well known book. A detailed review will follow later.

COMPANY REPORTS

East Pool & Agar.—As reported last month, this tin-wolfram-arsenic mine near Camborne, was shut down in February owing to the low price of metals and the high cost of wages and coal, though pumping is being continued in order that the property may be kept in good order. The report for the year 1920 shows that 74,433 tons of ore was raised and sent to the mill, 47,524 tons coming from the famous Rogers lode. The yields were 874 tons of tin concentrate, 46·8 tons of wolfram, and 500 tons of crude arsenic. The yield of tin concentrate per ton was 26·32 lb., and the calculated recovery in chemical assay was 68·8%. The amounts realized on the sale of the several products were £152,015, £1,024, and £22,728 respectively, making a total of £175,767, or 47s. 3d. per ton of ore milled. Other revenue brought the receipts to £180,310. The total expenses were £208,318, or 55s. 11d. per ton, so that there was a net loss for the year of £28,007. During the year, a large amount of development was done, with gratifying results, which are described in the extracts from Bewick, Moreing & Co.'s report given herewith.

On the 190-fathom level, the main east drive, on the Rogers Lode, was continued beyond the elvan, and for the 248 ft. driven disclosed ore averaging 48·5 lb. black tin and wolfram per ton over a width of 6 ft. A winze, at 520 ft. east, was started from the above drive and sunk 24 ft. in ore averaging 34 lb. black tin and wolfram per ton for a width of 5 ft. A rise, at 636 ft. east, was also started from the main drive, and extended 83 ft. in ore averaging 81 lb. black tin and wolfram per ton for a width of 6 ft. On the 212 fathom level, the main west drive was advanced 161 ft., to a total of 948 ft., the ore disclosed averaging 34·5 lb. black tin and wolfram per ton for an exposed width of 6 ft. The main east drive was advanced 129 ft. through the elvan course, but has not yet reached the downward extension of the high-grade ore opened up beyond the elvan at the 190-fathom level. On the 240-fathom level, the main west drive was advanced 119 ft. to a total distance of 506 ft., the ore disclosed averaging 34 lb. black tin and wolfram per ton for an exposed width of 6 ft. An east branch drive (826 ft. north, 150 ft. west), off the north side of the main east drive, was started and advanced 58 ft. in ore averaging 27·5 lb. black tin and wolfram per ton over an exposed width of 5·5 ft. On the 252-fathom level, a main north cross-cut, for opening up the Rogers Lode at this level, was started and extended 735 ft. from East Pool shaft and intersected the following: At 80 ft. north, the Red Lode averaging 70 lb. black tin per ton for a width of 5 ft.; at 336 ft. north, Branwell's Lode averaging 45 lb. black tin per ton for a width of 5 ft. (Where met in higher levels these lodes usually have been unprofitable, but the values above stated indicate that probably an improvement is taking place in depth as has been experienced in adjoining mines); at 430 ft. north, a lode averaging 37 lb. black tin per ton for a width of 8 ft.; at 537 ft. north, a lode averaging 82 lb. black tin per ton for a width of 5 ft.

On the 255-fathom level, the Tolgus tunnel, driven east from the most easterly workings in the Agar section, encountered what is believed to be the Great Lode at a distance of 860 ft., and for the 11 ft. driven on the lode the ore averaged 84 lb. black tin and wolfram per ton over an exposed width of 8½ ft. The full width of the lode was subsequently exposed by a south cross-cut from the tunnel, and averaged 158 lb. black tin and wolfram per ton for 13 ft. wide. The Great Lode has been extensively mined in both East Pool and Agar sections for a length of 2,700 ft., and for many years was the most productive lode worked on the property.

The distance from the most easterly workings in the old part of the mine to the eastern boundary is 2,000 ft., and the values disclosed in the tunnel give reason to believe that the Great Lode in this section also will produce large tonnages of profitable ore.

Tehidy Minerals.—This company was formed in February, 1919, to acquire the mineral rights of the Tehidy (or Basset) estate, near Camborne, other than the mining rights belonging to the Dolcoath and East Pool companies; in the August following the mineral rights of the Lanhydrock (or Clifden) estate were acquired. Particulars of the Tehidy estate were given in the MAGAZINE for July, 1919, and of the Lanhydrock estate in April, 1920, in each case accompanied by an exploratory map. The report now issued covers the period from the registration of the company to the end of 1920. The delay in issuing the report is due to difficulties in connection with the transfer of the Tehidy rights. The accounts show an income of £12,892 from Tehidy dues and rents, and £14,588 from Lanhydrock dues and rents. The administration expenses were £10,744, and income tax absorbed £8,429. The net balance of profit was £9,621, which was carried forward. The company has taken a substantial interest in the Cornish Kaolin, Ltd., whose works are situated at Bodmin Road, and has sold to them a portion of its clay areas. Cornish Kaolin's pipe-line and railway sidings afford an outlet for the working of the company's extensive china-clay deposits on Bodmin Moor and form the foundation from which this development will proceed. The company has purchased, since the end of 1920, from H. D. Pochin & Co., Ltd., their well-known works situated at Burngullow, and the Halviggan clay pits which are on the company's property, and which are connected with the Burngullow works by a pipe-line. The acquisition gives an outlet to sidings on the railway for working the company's clay deposits at Halviggan and district. Both these works are situated on the Great Western main line and are near the china-clay port of Fowey.

South Crofty.—As recorded last month, the mine and mill of this tin-mining company at Camborne were closed on February 12 owing to the high cost of wages and materials and the low price of tin. The report now issued covers the year 1920. During this period 69,960 tons of ore was raised and treated, from which were extracted 589 tons of tin concentrate, 38 tons of wolfram, and 645 tons of arsenic. The value of these products was £145,913, or 41s. 8d. per ton of ore milled. The profit and loss account shows total credits of £153,420, and a net profit of £3,056. The costs at the mine were 35s. 8d. per ton. The yields per ton were 18·8 lb. tin concentrate, 1·22 lb. wolfram, and 20·68 lb. arsenic. As regards development, the results have continued to be satisfactory. In the deepest levels at 260 fm. and 290 fm. in Robinson's section, comparatively high assay-values have been obtained over portions of the ground, while two new lodes of some promise have been discovered. Now that all the mines in the district are closed, the question of individual or collective pumping has arisen. At South Crofty there is a likelihood of a considerable increase in the amount of water coming in if complete stoppage or certain alterations in methods were adopted at adjacent mines. Hence the necessity for collective action.

Robinson Gold.—This company was formed in 1887 to work an outcrop mine in the central Rand, and for many years the returns were large and the mine was the greatest gold mine of the world. J. B. Robinson was the first chairman, but the control soon passed to the Ecksteins and later to the Rand Mines group. The mine is near exhaustion, and for some years operations have subsisted on the treatment of low-grade ore. The report for the year 1920 shows that 475,400 tons, averaging 4·7 dwt. per ton, was raised and sent to the mil without sorting. The yield by amalgamation was 63,397 oz., and by cyaniding 40,229 oz., making a total of 103,626 oz., or 4·36 dwt. per ton. The revenue was £573,570, of which £143,103 accrued from the gold premium. The revenue per ton was 24s. 2d., of which 6s. 1d. was premium. The working cost was £487,367, or 20s. 6d. per ton, leaving a working profit of £86,202, or 3s. 8d. per ton. It is clear, therefore, that the mine exists on the gold premium. The shareholders received £82,500, the dividend being at the rate of 3%. The reserve in the Main Reef Leader and South Reef is estimated at 115,200 tons, not valued. There is a large amount of ore remaining in the Main Reef, but only small portions of it are of sufficiently high grade to warrant extraction. Ore is still being extracted from the old workings and by the reclamation of pillars, but the resources in this direction cannot be estimated. Thus the remaining life of the mine is difficult to forecast.

Rose Deep.—This company was formed in 1894 to acquire claims on the dip of the reef below New Primrose in the near east Rand. In 1909 the adjoining Glen Deep was absorbed. The control is with Rand Mines, Ltd. The report for the year 1920 shows that 713,431 tons of ore was raised, and, after the removal of 9% as waste, 643,600 tons of ore, averaging 5·4 dwt. per ton, was sent to the mill. The yield of gold by amalgamation was 101,142 oz., and by cyaniding 62,644 oz., making a total of 163,786 oz., or 5·09 dwt. per ton milled. The revenue from the sale of gold was £900,917, or 28s. per ton milled. The working cost was £679,898, or 21s. 2d. per ton, leaving a working profit of £221,018, or 6s. 10d. per ton. The proportion of the revenue accruing from the premium on gold is not specifically given, but it is stated that but for this premium the margin between revenue and expenditure would have been extremely small. The shareholders received £192,500, the dividend being at the rate of 27½%. The development work has continued to give satisfactory results, and the reserve is estimated at 3,060,040 tons averaging 5·1 dwt. per ton, as compared with 3,031,280 tons averaging 5·2 dwt. the year before.

Consolidated Diamond Mines of South-West Africa.—This company was formed in February, 1920, by the Consolidated Mines Selection group, to acquire the properties of the principal German diamond-mining companies operating in South-West Africa. The first annual report, now issued, covers the period from October 1, 1919, to December 31, 1920. Of the German companies, the Pomona, Koloniale, and Deutsche were the biggest producers. Operations were continued by the German companies until March, 1920, after which date the present company took control and rearranged the work accordingly. The accounts show an estimated profit of £128,365 for the period from October 1, 1919, to February 16, 1920. From February 16 to the end of the year the sales of diamonds brought an income of £1,455,143, and on December 31 the stock of 346,675 carats was valued at £416,208, being the cost of production. The mining expenses were £501,997, administration expenses £27,720, allowance for depreciation £123,996, interest on debentures £131,821, allocation to sinking fund for redemption of debentures £138,742, and payment to the Government £404,237. The balance of profit for February 16 to December 31 was £249,973. Owing to the uncertainty of the diamond market no dividend has been declared. The engineer gives the figures for the output of diamonds during 1920 as 545,027 carats, ob-

tained by treating 1,106,729 cubic metres of ground.

Associated Northern Blocks. This company was formed in 1899, as a subsidiary of the Associated Gold Mines of West Australia, to work the Iron Duke and other properties at Kalgoorlie, West Australia. For many years satisfactory profits were earned. Later the property was let on tribute. In 1910 the Victorious mine at Ora Banda was acquired. This property has also been let to tributers. The report for the year ended September 30 last shows that 17,316 tons was raised by the tributers at the Victorious, which yielded gold worth £32,757 at par, and that 14,981 tons was raised by tributors at the Iron Duke, yielding gold worth £45,622 at par. After the receipt of the premium on gold, £11,717, the profit accruing to the company was £13,756, out of which £3,419 was written off for development and depreciation. The balance brought forward from the previous year was £21,997, so that the disposable balance of profit at the end of 1920 was £32,334. Out of this, £17,500 was distributed on March 31, 1920, the dividend being at the rate of 1s. per share, tax paid. In 1910 the company purchased the El Refugio mine in Zacatecas, Mexico. This was subsequently let on lease, and the report now states that the lessee has commenced the erection of a milling plant.

Globe & Phœnix.—The report of this celebrated gold-mining company operating in Rhodesia, covering the year 1920, gives no details of the ore mined and treated. The profit and loss account shows an income of £379,880 from the sale of bullion at par value, to which is added £153,457 received as premium on the sale of the gold. The profit for the year was £344,042, of which £78,945 was paid out for income tax and corporation tax, £100,000 was placed to development reserve, while £240,000 was distributed as dividend, being at the rate of 120%. The ore reserve is calculated at 93,852 tons averaging 31 dwt. per ton. The last previous report as regards ore reserves was published in October, 1919, when the figures were 143,333 tons averaging 30 dwt. At the end of 1918, the figures were 159,913 tons averaging 29·4 dwt., and at the end of 1917, 184,053 tons averaging 28·9 dwt. It is clear that mining operations have depended on the ore reserve for some time. The present report on development work received from D. P. McDonald indicates improvements in the results at various points, but he confesses that more good luck is desirable.

Jos Tin Area (Nigeria).—This company was formed in 1910 to work a number of tin-mining leases in Nigeria. The report for the year ended July 31, 1920, shows that 143 tons of tin concentrate was won, as compared with 233 tons the year before, the fall being mainly due to shortage of labour. For the six months ended January 31, 1921, the output was 131½ tons. Owing to the present low price of tin, the rate of output has been reduced and the staff has been cut down considerably. The profit for the year under review was £1,214, which was carried forward. In writing of this company last October, we referred to a report for the year ended July 31; this report was for the year ended July 31, 1919, not July 31, 1920.

Hollinger Consolidated Gold Mines.—The tenth annual report of the leading gold-mining company operating at Porcupine, Ontario, for the year 1920, shows that 650,205 tons of ore was sent to the mill, averaging \$9·93 per ton. The gold produced was valued at \$6,219,664, or \$9·56 per ton. The receipts during the year including the premium on gold were \$6,939,628, and \$222,982 was received as dividends and interest. The working cost was \$3,144,328, or \$4·83 per ton of ore treated. Taxes absorbed \$225,940, \$445,985 was written off for depreciation of plant, \$408,250 was written off development account, and \$260,872 was written off investments. The net profit was \$2,675,274, of which \$2,214,000 was distributed as dividends. The ore reserve was estimated at 3,294,005 tons, averaging 11 dwt. per ton. Two years earlier the reserve was estimated at 4,275,570 tons averaging \$9·00 per ton. In the later estimate all ore lower than \$6·00 has been eliminated. Virtually the whole of the calculated reserve is above the 800 ft. level. The lodes have been proved below this, and down to 1,350 ft., but no estimate of their contents has yet been made.

Mexico Mines of El Oro.—This company has worked a gold mine at El Oro, Mexico, since 1904. As the mine is fully developed, a subsidiary exploration company was formed a year or two ago and the control of other properties has been acquired, but owing to adverse conditions in metals the new ventures are in abeyance at present. The report for the year ended June 30 last shows that 138,710 tons of ore was milled, averaging \$11·36 in gold and 8·39 oz. silver per ton. The yield of gold was \$1,435,381 and of silver 972,934 oz., being recoveries of 91% and 83·5% respectively. The accounts show an income of £533,808 from the sale of the gold and silver, and a net profit of £196,579, out of which £189,000 has been distributed as dividends, being at the rate of 90% tax paid. Developments continue to disclose ore, and during the past year blocks of ore higher in silver than gold have been found on the 3rd, 4th, and 9th levels. The reserve is estimated at 350,100 tons, averaging \$10·92 gold and 8·82 oz. silver per ton, a decrease of 29,100 tons in tonnage and \$0·68 in gold content, and an increase of 0·22 oz. silver, as compared with the figures a year before.

San Francisco Mines of Mexico.—This company was formed in 1913 to acquire silver-lead-zinc mines near Parral, Chihuahua, Mexico, previously worked by the San Francisco del Oro company. The report for the year ended September 30 last shows that the concentrator, enlarged to a daily capacity of 100 tons toward the end of 1919, was at work as continuously as Mexican conditions allowed. During the period under review 25,087 tons of ore was treated in the concentrator, averaging 9·4% lead, 20·2% zinc, 0·8% copper, 1·28 dwt. gold, and 20 oz. silver. The yield of lead concentrate was 5,901 tons, averaging 30·4% lead, 21·4% zinc, 3 dwt. gold, and 41 oz. silver. The recovery of the lead was 77% and of silver 47%. The output of shipping ore was 8,064 tons, averaging 8·76% lead, 18·45% zinc, 1·75 dwt. gold, and 33 oz. silver, together with 644 tons of oxidized ore averaging 6·56% lead, 1½ dwt. gold, and 19 oz. silver. The total received for the concentrate and shipping ores was 1,657,074 pesos. The profit made by the company was £33,149, as compared with a loss of £40,900 the year before. Plans are in hand for the extension of the concentrator to a capacity of 250 tons per day. The finances of the company are to be rearranged so that payment of interest on debentures may be suspended for three years, and funds arising from profits thus released for the requirements of the mine.

British Aluminium.—This company operates four hydro-electric aluminium smelting works, two of them being in Scotland, and two in Norway, and it also owns rolling mills in Stafford and Lancashire. The report for the year 1920 shows a net profit of £137,611, of which £118,077 has been distributed as dividend, being 6% on the preference and 10% on the ordinary shares. The company does not give particulars of the output of aluminium. The works have been considerably extended during the year, and were fully employed. Since the close of the year, however, the fall in consumption has been such that it has been necessary to curtail seriously the output at the various works.

THE new village built by the Anglo-Persian Oil Company at Skewen, near Swansea, has been christened "Llandarcy," in memory of the late Mr. W. K. D'Arcy. This village is intended for the accommodation of employees at the company's great oil-refinery.

IT is often complained that, though the American economic geologists have contributed in no small degree to the elucidation of many problems connected with ore deposits, their knowledge of the world outside their own country is restricted. An example of this contention is provided by the fact that the title page of *Economic Geology* mentions as one of the associate editors of that magazine Dr. E. T. Mellor, of "Johannesville."

WE take pleasure in announcing that a series of special lectures on the zinc industry are to be given at the Sir John Cass Technical Institute, Jewry Street, Aldgate, by Messrs. J. C. Moulden and E. A. Smith. Mr. Moulden will give two lectures on "Modern Developments in the Zinc Industry," on May 25 and June 1, and Mr. Smith will deliver three on "Industrial Applications of Zinc," on June 8, 15, and 22. The lectures will each last for an hour, from 5.30 to 6.30 p.m., and the entrance fee for the course is 10s. 0d. The Institute is to be congratulated on having secured, during the last few years, the services of many eminent authorities willing to help the cause of education by giving freely from their store of experience. The Institute is doing excellent work in providing facilities for evening study, and these facilities deserve to be more widely known in mining and metallurgical circles.

ONE of the outward and visible signs of the new spirit in India is the publication of the *Journal of Indian Industries and Labour*, a quarterly magazine issued under the auspices of the Indian Government. The object of this magazine is to disseminate trade and technical information between the various provinces of India, which under the new regime are largely independent of each other in policy and administration. In addition, it is intended to issue separate Bulletins on special subjects. The first number contains articles on the possibilities of industrial development in the Central Provinces and Berar, welfare work in Bombay cotton mills, researches in tanning, the gilt wire and tinsel industry at Burhanpur, trade disputes in Bengal, industrial education in Madras Presidency, and the commercial aspects of bauxite. The last named is written by Dr. J. Coggin Brown, a member of the Indian Geological Survey who has, during the last year or so, done excellent work in London in bringing Indian mineral resources to the notice of the commercial community. Sir Thomas Holland supplies a foreword to this first number, recounting the circumstances under which the *Journal* has been founded. We take this opportunity of recording our appreciation of the services rendered by Sir Thomas and his associates in piloting India through a difficult transitional period.

THE board of directors of the Burma Corporation have made arrangements to purchase the control of a number of English lead smelters. This control was secured recently through the instrumentality of Mr. R. Tilden Smith, who formed a company called the Associated Lead Manufacturers, Ltd., for the purpose. Mr. Tilden Smith, it will be remembered, has a very large interest in the Burma Corporation. The lead firms controlled by the Associated company are: H. J. Enthoven & Sons; Walkers, Parker, & Co.; Locke Lancaster & W. W. & R. Johnson & Sons; Foster, Blackett, & Wilson; and Alex. Fergusson & Co. This list includes all the chief English lead firms except Cooksons and Locke, Blackett & Co. The object of the Burma Corporation in acquiring the control is to provide an outlet for its lead concentrates and the marketing of products such as pig, sheet, and pipe lead and the various lead pigments. The policy is to smelt some of the concentrates locally and to dispose of the products in the East; and to ship the remainder to England for treatment by the firms named. The purchase price of the control is £400,000 in Burma Corporation debentures and £100,000 in cash, the latter being devoted to the purchase of Associated shares at par. It is believed that this policy will be cheaper and less disturbing to the lead trade than an enlargement of the Corporation's smelter and treatment works, while a firm of accountants show, by a ten years' record of the financial results obtained by the individual lead firms, that the investment in the shares of the Associated company should be lucrative. For some reason, which we shall not attempt to explain, this proposal was placed before an in-

formal meeting of shareholders without any indication of its nature having been given in the convening circular. Moreover, the representatives of the press were rigidly excluded. The attending shareholders were taken by surprise, and were further mystified by Mr. F. A. Govett's speech, in which he began by stating his objections to the scheme and ending by recommending shareholders to adopt it. During subsequent days Sir Trevredyn Wynne, the chairman, received many protests and deputations, finally promising to provide further information before completing the deal.

IN his paper on ore deposits of igneous origin read last month before the Cornish Institute of Engineers, Dr. R. H. Rastall drew attention to the question of searching for platinum in the serpentines of the Lizard district. Recent publications by Du Parc and Orueta have provided definite proof that the original home of the platinum group of metals in the Ural Mountains and in Spain is in the serpentinized ultrabasic rocks, and the alluvial platinum of Colombia is associated with boulders of serpentine. The possibility of platinum being found at the Lizard once more arises. Here there are large areas of serpentine, but no recorded assay shows any platinum content. The amount of platinum in the rocks is so small that failure to find it is not to be wondered at. Dr. Rastall suggests that a systematic search for alluvial deposits that have undergone natural concentration should be made, to be followed by extensive panning tests and assays. There are not many streams draining the Lizard serpentines, but it would be worth while to test the bedrock of such as there are.

IN another part of this issue we reprint the report of a committee of the Geological and Mineralogical Societies on the standardization of British petrographic nomenclature. Most geologists and mining engineers will accept the recommendations, though perhaps some will query the wisdom of abandoning the term "diabase." We understand, however, that its disuse was advised owing to its ambiguity. In early days the word was applied to somewhat decomposed basalts of Pre-Tertiary age, and in this sense the word was used largely in Germany. Later, Harker used it to denote basic intrusives of hypabyssal type, but afterward he replaced it by "dolerite." At the present time, when used by most of the scientific petrologists, it implies the idea of more or less decomposition, and thus a "diabase" may often be a "rotten dolerite." On the whole, therefore, the committee advised the retention of "dolerite" and the disuse of "diabase." There is one point in connection with the report that is distinctly comforting: no new terms are recommended. Perhaps in the not distant future it will be possible for the committee to get into contact with American petrographers. Attempts in this direction have proved fruitless hitherto, but as it is obviously desirable that there should not be two nomenclatures, one English and the other American, perseverance in this matter is essential.

Gold Stealing.

A little over two years ago we referred in these pages to the public scandal of gold stealing, which continuously takes place at the Kalgoorlie mines. It is an undoubted fact, and well known to the managers and metallurgists, that these mines have been losing at least £100,000 of gold annually owing to this pilfering of rich ore and crude gold. It is not necessary here to recapitulate the case of the mine-owners, or to show how the Government of West Australia has steadily refused to adopt the recommendations of the Commission on Gold Stealing appointed over fourteen years ago, and has objected to taking any strenuous action calculated to abate the nuisance. Our article in 1918 was written with the avowed object of stirring the Government, and of assisting the West Australian Chamber of Mines and the mine-owners in their campaign of self-protection. But still nothing is done, and the malpractices flourish as ever. The goldfields police, on the other hand, continue to act as alertly as the law allows them, and they have been successful in scotching two offenders. The first case occurred toward the end of 1919, when a man operating at the sand-treatment plant on Burbank's Birthday Gift mine was convicted of buying stolen gold and rich ore. This man had been suspected for some time of conducting a shady business of this sort, for the output of gold from the plant was obviously much in excess of any possible gold content of the material treated; but it took the police a long time to obtain evidence of a character that would satisfy the local courts. If there had been a law permitting the police to sample and assay the material fed to the plant there would be little difficulty in detecting frauds of this character. It is one of the contentions of the mine-owners that all treatment plants of this description should be open to official inspection at any time. Undoubtedly such a condition would act powerfully in suppressing bogus custom plants.

Another of the rare instances of conviction occurred in October last, when an employee of the Golden Horse-Shoe company was caught in the act of stealing 2½ lb. of gold slime. On being searched, his clothing was found to contain a number of unusual pockets evidently specially designed for receiving small and large amounts of purloined material. At his home were discovered a number of bags which bore the appearance of having contained gold slime. This man had been in the service of the Golden Horse-Shoe for ten years, and had previously been employed at the Ivanhoe for fourteen years. During the whole of that period his character had always been apparently above suspicion, yet the circumstances under which he was detected pointed to a systematic and carefully designed plan of campaign. It might be supposed that here was the opportunity for an exemplary punishment that would act repressively. But no! the magistrate referred feelingly to the fact that the culprit had a wife and children, and let him off with two months' imprisonment.

These thefts, as we have said, have been going on throughout the Kalgoorlie goldfield ever since the deposits were first exploited. The ownership of the mines is largely in the hands of English investors. In many quarters, not only in Australia, but elsewhere, there is a popular prejudice against investors, who it is ignorantly alleged neither put the gold into the rocks nor contributed toward getting it out. When the shareholders are over the seas this prejudice becomes more marked, and the means for combating it correspondingly diminishes. Apparently the authorities in West Australia are not sympathetic with English investors, or at any rate do not care to take any public step to show it. So the scandal remains, and presumably will never be checked. At the present time, however, when increased wages and costs are narrowing, if not annihilating, the margin of profit, it seems a pity that nothing can be done to stop this illegitimate reduction of income, even if only the interests of the wage earners are considered.

The Institution of Mining and Metallurgy.

At the thirtieth annual meeting of the Institution of Mining and Metallurgy, held on the 21st of last month, two important announcements were made with regard to the future of the society. In the first place, the home is to be moved from Finsbury Circus to City Road; and second, a close relationship has been arranged with the Institution of Mining Engineers, the society in Victoria Street.

As regards the approaching removal from Finsbury Circus, it will be remembered that this house and the land on which it stands was bought seven years ago, after the Institution had had ordinary offices, first at Broad Street House, and later in Salisbury House. At the time the house was purchased, the hope was that the home would be a permanent one, though the Council were not unaware of the fact that the property was old, and that it is situated in a position suitable for a modern office building. Finsbury Circus used to be composed almost entirely of houses such as that which the Institution occupies. Gradually these have disappeared, to be replaced by Salisbury House, London Wall Buildings, Broad Street Place, River Plate House, and No. 16, usually known as Shell-Mex. The remaining block of old property, together with similar property round the corner in West Street and Finsbury Pavement, has now been bought by the Eastern Telegraph Company, which is intending to erect a modern building similar to Electra House on the opposite corner of West Street and Finsbury Pavement, a house which it built about twenty years ago. In order to secure the Institution's premises and the land on which it stands, the company had to offer sufficiently attractive terms to induce the Council to agree to a removal. Here, however, a serious difficulty arose, for owing to the present congested state of office accommodation in the City no suitable alternative home could be obtained. Finally, in default of any better proposal, the Council agreed to accept the company's offer of Cleveland House, a building in City Road. Thus the Institution obtains the free occupation of this building for the remainder of the lease, 38 years, at a nominal ground rent, together with a sum of £20,000 in cash, and the expenses of removal and redecoration. The building is large and commodious, and the floor space is more than twice that at Finsbury Circus. The Council are, of course, justified in congratulating themselves on a satisfactory financial deal and on obtaining increased accommodation, but, on the other hand, they have to admit that the neighbourhood to which they are migrating is both inconvenient and unpleasant. The new home is nearly a mile from the old one, and is situated half way toward the Angel at Islington. It was originally built as the Vestry Hall of St. Luke's parish. Behind it is St. Luke's Workhouse, in Shepherdess Walk, and beside it is the Police Station, and also the Eagle, of which the jingle says: "Up and down the City Road, in and out the Eagle,

that's the way the money goes, Pop goes the weasel." It is also near Sir Thomas Lipton's cheap restaurant, known as the Alexandra Trust Dining Rooms; and not far away is St. Luke's Hospital for Lunatics. We do not exactly know why, but there seems to be something humorous in connection with what the Scotsman would call the amenities. There is no gainsaying the fact that the hearts of most members of the Institution fell into their boots when the news of the removal was broken to them. But it is no use blaming the Council, for they have equally suffered this anatomical rearrangement. Criticism is worse than useless, for it is not likely that anyone would have been able to discover a more acceptable solution of the difficulty. Perhaps it would be more heroic to view the position with a certain amount of pride, comparing the Institution to the People's Palace, Toynbee Hall, or the Oxford Settlement, shedding the light of culture and learning among the less-favoured classes of the population. In any case, it is more than probable that the new home will prove to be only a temporary makeshift.

The other matter to which reference was made at the meeting is the closer co-operation between the Institution of Mining and Metallurgy and the Institution of Mining Engineers. The latter society deals chiefly with the mining of coal and iron in this country, while the former is devoted to metals and minerals other than iron and coal. According to the view taken by each individual, the two societies may be supposed best entirely independent, or, owing to the complementary nature of the subjects, best amalgamated or at any rate drawn into closer co-operation. The Institution of Mining Engineers is in the nature of a federation of a number of local societies in this country, of which the North of England Institute has taken the most prominent part. It was originally hoped by the North of England Institute that the Institution of Mining and Metallurgy would join the federation, but the Institution considered that its aim and scope were so different from those of the provincial societies as to make such a step inadvisable. It may be said here that all these questions depend largely on the temperament of those who direct the fortunes of the societies. Thus it is probably a pity that the personal element prevented fusion or co-operation in those days. The matter was revived recently by certain engineers interested in both societies, of whom it is allowable to mention Sir John Cadman, and the Institution of Mining Engineers once more approached the Institution of Mining and Metallurgy, this time, however, in more deferential spirit. The course of negotiations need not be described here; suffice it to say that the two institutions have agreed to act together, without losing their identities, or interfering with their Royal Charters. The Institution of Mining Engineers is to move from Westminster and share the new home of the Institution of Mining and Metallurgy, and Mr. C. McDermid, the secretary of the Institution of Mining and Metallurgy, is to be also secretary of the Institution of Mining Engineers. Having thus effected this important preliminary step, both institutions will require time to get their breath, but it is obvious that before long a further settlement will have to be effected. The Institution of Mining Engineers is an unwieldy body, and has rather lost grip of affairs in recent years since the death of Mr. Walton Brown. Something ought to be done to abolish the local societies as such, and, if necessary, transform them into local sections of the mother society. Then it is desirable that the South Wales Institute of Engineers should be drawn into the circle. It is also to be recommended that the Institution of Petroleum Technologists should be associated in some way with the other two institutions. Afterwards the National Association of Colliery Managers and the Association of Mining Electrical Engineers should be approached, with a view to their ultimate extinction and the absorption of their chief activities. As for co-operation with societies in other parts of the Empire, this is foreshadowed in the report of the Council of the Institution of Mining and Metallurgy. There are other possible steps toward unification of interests connected with the mineral industries of the Empire, but the time for these has not yet arrived. In the meantime, it is the plain duty of all members of the Institution of Mining Engineers and the Institution of Mining and Metallurgy to see that the co-operation of the societies achieves the end desired, namely, the strengthening of the status of the mining engineer.

Rand Mining Results.

At this time of the year most of the companies operating on the Rand issue their annual reports. Our Mining Digest for this month and last contains abstracts giving the main features of the results obtained. These abstracts may be conveniently supplemented by a brief summary of the impressions gained by reading these reports. Two facts stand out prominently. In the first place, cost of production has continued to go up during 1920, and

many of the reports indicate the likelihood of further advances. On the other hand, some engineers are inclined to believe that a maximum has been reached, and that there are hopes for reductions before long. Judgment on this point is naturally influenced by the fact that there are enormous holdings of enemy shares hanging over the market, shares now in the hands of the British and Union Governments, who are trying their best to induce the financial houses to absorb them. Under such circumstances it is only business on the part of the financial houses to lay stress on the conditions most deterrent to a rise in share quotations. The other fact to which we refer is that two-thirds of the producers are existing largely if not entirely on the premium received for their gold.

In earlier years, when writing of Rand results, we made a practice of comparing the outputs and profits of the three great consolidations, Crown Mines, Randfontein Central, and East Rand Proprietary. The last occasion on which we reviewed the results of these companies' operations was in May, 1916, when the figures for 1915 were analysed and compared. In that year the outputs of gold were 763,063 oz., 680,697 oz., and 614,030 oz. respectively. For 1920 the figures were 672,738 oz., 409,669 oz., and 400,495 oz. During the interval, Crown Mines has been working steadily on its original development scheme, but the increased costs and comparatively low grade of the ore have prevented the full benefit being obtained from the excellent mining organization adopted. Randfontein Central has changed hands, and, under the auspices of the new controllers, the method of attacking the ore has been radically changed. The advantages to be obtained by this rearrangement of methods are now becoming obvious, and the large reserves of fair-grade ore point to increased outputs and profits. At East Rand Proprietary, the ore position has gradually become worse during the last few years, and profits have not been made; in fact, the very existence of the mine has been in constant jeopardy.

In 1915 the individual outputs of these three big consolidations were more than twice as great as that of any other mine on the Rand. In 1920, we find Crown Mines still the largest producer of gold with 672,738 oz., but the other two mines have been outstripped in the race by Government Areas with 600,154 oz., and New Modderfontein with 531,304 oz. Of other notable results in 1920, there may be mentioned City Deep with 351,363 oz., Modderfontein B with 312,218 oz., Van Ryn Deep with 306,614 oz., Modderfontein Deep with 267,873 oz., and Brakpan with 253,664 oz. Of the above-mentioned mines, all but East Rand Proprietary have excellent prospects. Other mines doing well are Meyer & Charlton, Geduld, and Springs, though the first-named is fully developed, and has no speculative prospects. Of new mines, Modderfontein East is producing and its prospects are fair. New State Areas and West Springs are in course of development, but work has not got much further than shaft-sinking. At Daggafontein, the results of development have not been very satisfactory so far, and operations are suspended for the present until further capital is forthcoming.

A number of mines have ceased production during the year, namely, Jupiter, Simmer Deep, Knights Deep, Village Main Reef, Princess Estate, City & Suburban, and New Heriot. Of producing mines not mentioned already, only the gold premium has made the financial position sound; in some cases the premium has made dividends possible, while in other cases the premium has barely kept the mines alive. Langlaagte Estate, Consolidated Main Reef, Kleinfontein, Robinson Deep, Rose Deep, and Village Deep appear to have plenty of life left in them, provided conditions are favourable, but Aurora, Consolidated Langlaagte, Durban Deep, Ferreira Deep, Geldenhuis Deep, Knight Central, Luipaard's Vlei, New Goch, New Primrose, New Unified, Nourse, Robinson, Roodepoort United, Simmer & Jack, Van Ryn, West Rand Consolidated, Witwatersrand (Knights), Witwatersrand Deep, and Wolhuter are either near the end of their reserves or are in too poor ground to pay dividends. But old mines die hard, and plenty of pluck is exhibited in keeping them going on the Rand.

The foregoing remarks may impart some idea as to the prospects of most of the mines on the Rand. There are many factors making for success or otherwise, but it must be remembered that comparative richness of the ore worked has now, as always, more influence on profits than large-scale working. The biggest profits on the Rand during 1920 have been made by the mines working rich ore, such as Meyer & Charlton, Van Ryn Deep, Modderfontein Deep, New Modderfontein, and Modderfontein B. To these and to Government Areas, City Deep and Crown Mines, Geduld, Brakpan, and Springs, large mines but of not quite the same grade, must be looked for profits during the next year or two, with hopes for Randfontein Central, New State Areas, and West Springs coming forward in the near future.

REVIEW OF MINING

Introduction.—The coal strike still continues and the manufacturing industries of the kingdom are at a standstill. The settlement can hardly come by any other way than a substantial reduction of wages, and the employees in all departments of trade are fully aware that they also must submit to reductions. It is a good augury that wages are being cut down drastically in the United States. In the meantime base-metal mining has shrunk to small dimensions, but a buoyant hope pervades the profession and the markets that things will be all right again soon.

Transvaal.—Précis of the reports of a large number of Rand gold-mining companies are given elsewhere in this issue, and also a general review of the results of output. There are one or two points of interest in these reports to which attention may be drawn. The deepest working on the Rand at present is in Village Deep, where the shaft is now 6,059 ft. vertically below outcrop. At City Deep, the mill was worked to full capacity for the first time, this having been made possible by the absorption of the underground staff, white and native, from the City & Suburban. In the Far East Rand, perhaps the most recent development of importance is in Geduld; here a large amount of high-grade ore has been discovered in the south-western part of the property adjoining New State Areas, and the prospects for finding further ore of the same quality are excellent.

The Union Government has held a statutory inquiry into the closing down of Daggafontein, when Mr. Carl Davis, the consulting engineer, gave a full account of the mining difficulties that had supervened. All sorts of suggestions have been made by outsiders for raising further working capital, including a proposal that the Government should lend some of its huge profits accruing from Government Areas, and another that the Government should issue premium bonds.

Rhodesia.—The gold returns for March reflect the result of the strike, the figures being 31,995 oz., as compared with 40,816 oz. in February, and 45,779 oz. in March, 1920. The other returns were as follow: Silver 10,085 oz., copper 248 tons, arsenic 21 tons, coal 33,084 tons, chrome ore 11,767 tons, asbestos 1,990 tons, mica 8 tons, and diamonds 21 carats.

The depression in the copper market has had a serious effect on the financial position of Falcon Mines, which was never very strong. At the meeting held early this month, it was announced that £50,000 was required to pay income tax, debenture interest, and other liabilities, while over £70,000 would have to be provided next year for the redemption of the balance of the debentures. Unless the price of copper improves before long there will be no alternative but to stop work at the mine. The report now issued covers the year ended June 30, 1920, and shows that 168,675 tons of ore was treated for a yield of 2,706 tons copper, 30,942 oz. gold, and 61,812 oz. silver, realizing £452,298. The working cost was £350,599. After taxes, debenture and other interest, and other items were deducted, the profit for the year was £66,759, out of which £30,000 was devoted to debenture redemption. During the six months July to December, 92,188 tons of ore yielded 1,556 tons of copper, 17,604 oz. gold, and 35,445 oz. silver. The ore reserve at June 30, 1920, was estimated at 609,000 tons averaging 4·85 dwt. gold and 2·07% copper. The bottom levels are in disturbed ground, and a good deal of development will have to be done to prove them in depth. On the 11th level the ore-body is estimated to be 220 ft. long and 40 ft. wide, averaging 5 dwt. gold and 1·9% copper, together with a western shoot 70 ft. long and averaging 6·6 dwt. gold and 1·9% copper over 57 inches. On the 12th level, 180 ft. of ore 33 ft. wide and averaging 3·7 dwt. gold and 2·45% copper has been proved, but this is not the full extent.

In February we briefly recorded that developments in depth at the Lonely Reef gold mine continue good. The report for 1920, now to hand, shows, however, that though some very rich ore was discovered during the year in the upper levels, the ore disclosed in the bottom levels is of considerably lower grade than that developed during the previous year. Consequently the reserve, while being maintained as to tonnage, is lower in gold content, the actual figures being 202,845 tons averaging 20·8 dwt. per ton, as compared with 199,739 tons averaging 23·54 dwt. Another point of interest in connection with the bottom workings is that the dip is gradually decreasing, and consequently the cross-cuts from the incline shaft which follows the pitch from the 9th level become longer at each succeeding level. It is intended therefore to sink a new incline under the lode at the 24th level. The consulting engineer also mentions that the supply of firewood suitable for boiler furnaces is exhausted, but that there is abundance of wood suitable for the produc-

tion of gas. It has therefore been decided to substitute steam power by gas engines.

West Africa.—The report of the Fanti Consolidated Mines, Ltd., for 1920 makes reference to the progress made in developing the manganese property at Dagwin. This property was to have been floated as a subsidiary, but the attitude of the Inland Revenue authorities with regard to Excess Profit Duty made it inadvisable to pursue this policy. It was therefore decided that Fanti Consolidated should do the development and equipment itself. Additional shares were issued for this purpose, and an output of 200,000 tons per year has been arranged. The company has a contract for the delivery of 100,000 tons per year for five years at a guaranteed minimum profit of 7s. 6d. per ton, and this contract is renewable for two further periods of five years each. The total amount of ore shipped during 1920 was 41,546 tons.

Nigeria.—The Nigerian Chamber of Mines has been in communication with the Nigerian Government with a view of securing some measure of assistance or protection during the present times of stress. As a result, certain temporary concessions as regards rents, royalties, and working conditions have been granted by the Government: (1) Mining lessees to be released temporarily from labour obligations; three months' notice to be given by the Government before these obligations are again inforced. (2) Until further notice mining rentals on land not worked to be reduced to 2½% of existing rentals, and mining rentals on land worked to 50% of existing rentals. (3) A new and more favourable scale of royalties to be adopted which will afford appreciable relief during the time that the present low price of tin continues. Efforts to obtain a reduction of railway rates on the transport of tin concentrates were not successful.

The Mongu company announces that operations are now confined to the bucket-dredge, and that sluicing and calabashing have been suspended during the depression in the tin market. Prospecting also has been stopped, as the company has extensive proved areas. A small amount of tributing is being continued. The report for 1920 shows that 350 tons of concentrate was won by sluicing and calabashing and 140 tons by dredging. The sales of concentrate brought an income of £98,925, and the profit was £39,263, out of which £9,000 has been allocated for taxation, and £11,607 has been distributed as dividend, being at the rate of 12½%. Under present conditions the directors are wisely keeping a large balance in hand.

Australia.—The output of gold throughout Australia for the year 1920 is given in the accompanying table, together with the figures for 1919. It will be seen that all the states show a diminution except Victoria. In the latter state the revival of activity at Bendigo has been the chief factor in an advance.

	1919. Oz.	1920. Oz.
Victoria	135,428	152,792
New South Wales .. .	65,839	48,907
Queensland ..	120,885	114,181
West Australia	734,067	617,842
South Australia . ..	3,224	3,000
Northern Territory	829	800
Tasmania	11,000	6,170
	1,071,272	943,692

The Kalgurli ore is now exhausted, and the directors have given instruction that the mine shall be closed and the assets realized. This mine was smaller than some of its neighbours at Kalgoorlie, but it was highly profitable, having returned excellent dividends from 1903 to 1916. It is a grateful duty to record that the direction and the management were always of the best.

The Ivanhoe treated 154,920 tons of ore during 1920, for a yield of 57,471 oz. of gold, figures not greatly different from those of the previous year. The gold premium, however, brought a larger income, £346,293 being received, of which £102,000 was premium, as compared with £291,219, of which £41,220 was premium; while, on the other hand, the working cost was 3s. 7d. per ton higher. The net profit was £65,725, out of which £65,000 has been distributed as dividend, making 6s. 6d. per £5 share. It will be seen that, but for the premium on gold, there would have been a loss on the year's working. As regards development, ore is still being found in the operating levels, but in the workings below 2,420 ft. prospecting still gives negative results. The reserve is estimated at 861,786 tons averaging 34s. 4d. per ton, par value, as compared with 972,387 tons averaging 33s. 9d. per ton the year before. It is clear that, with the labour position as it is, the future of the mine depends entirely on the gold premium.

Another dispute has occurred at Kalgoorlie with the firewood cutters, so some of the mines, including the Ivanhoe and Golden Horse-Shoe, were shut down for a short time.

The Fremantle Trading Company, which works silver-lead mines in the Northampton district and also a custom smelter, has been obliged to cease smelting owing to the closing-down of the outside mines. The company's own mines are also necessarily closed, but are being kept in good condition.

The output of metals and minerals in Tas-

mania during the year 1920, together with their market value, are given in the following table:

		Output.	Value £.
Gold	oz.	6,246	29,796
Silver	oz.	623,359	166,797
Osmiridium	oz	2,009	77,114
Lead	tons	3,855	142,268
Copper	tons	4,791	528,237
Tin	tons	1,310	369,362
Coal	tons	75,429	64,005
Wolfram	tons	71	13,626
Scheelite	tons	105	17,905
Bismuth	cwt.	2	9
Shale	tons	140	172
Iron Pyrites	tons	4,440	7,346
Barytes	tons	1,048	4,136

India.—A new agreement has been made between the gold mines and the Indian Government with regard to the disposal of the gold produced. This is the third arrangement made during the last two years. It is gratifying to know that the mines will by its means reap full benefit from the premium, and be no longer hampered by regulations which were in the nature of halting concessions.

The Ooregum is the deepest of the Indian gold mines. In Taylor's section a winze is being sunk on the 62nd level, which is 5,700 ft. vertically below outcrop. In Oakley's section work is being done on the 64th level, 6,000 ft. vertically below outcrop. In both cases fairly good results are being obtained. In Bullen's section the lode contains much pegmatite, which is barren, but the quartz ore gives good assays.

At the Nundydroog, 102,431 tons of ore was treated during 1920, and 71,531 oz. of gold was extracted, realizing £365,568. The working profit was £109,781, of which £35,962 was written off for plant and shaft-sinking, £31,000 was paid as income and corporation tax, and £14,150 was distributed as dividend, being at the rate of 6d. per 10s. share. As will be remembered, the company was reconstructed in November last in order to provide the capital required for deeper sinking.

The Cordoba Copper Company disposed of its mines in Spain over a year ago and took options on copper properties in Chota Nagpur, India. The report now issued shows that a large amount of prospecting has already been done. At the Surda properties two shafts are being sunk in the neighbourhood of the old workings. At Mosaboni two old shafts are being continued and two new ones are being sunk also; one of these has already intersected a lode at 100 ft. showing copper sulphides. At Dhobani three shafts are being sunk, and one of them is in a lode containing oxidized copper ores. It will be remembered that these properties formed part of the original options acquired by the Cape Copper Co., whose Rakha Hills mine is to the north-west. The apatite deposits described by Mr. Murray in the April issue are to the south-east, and the village of Mosaboni is marked on the map accompanying his article.

Borneo.—The British-Borneo Petroleum Syndicate is issuing 260,000 new shares of 10s. each, thereby increasing the capital from £120,000 to £250,000. The object of the new issue is to enable the company to take advantage of many opportunities for profitable business. The syndicate has concessions in British North Borneo, Brunei, and the Klias Peninsula. The D'Arcy Exploration Co., a subsidiary of the Anglo-Persian Oil Co., had an option on these properties, except part of the British North Borneo concessions; recently it has announced its intention of exercising its rights in British North Borneo and of making full geological examination, but it has renounced its rights on the Brunei and Klias Peninsula concessions. The latter properties are not sufficiently extensive for the Anglo-Persian, but they are now being considered by other parties. The part of British North Borneo not covered by the D'Arcy Exploration Co. is leased to the Kuhara Mining Company, of Japan, which is conducting extensive exploration. The syndicate has interests in the Apex (Trinidad) Oilfields, Ltd., and in the London & Midland Oil Company, which is operating properties in Roumania. The syndicate also has interests in Tuxpam, Mexico, and in South America.

Cornwall.—The passing of Tincroft is an event to be recorded with mixed feelings. It is difficult to say when this mine was originally opened, but records show that on re-starting in 1833 the depth was 136 fathoms. It was amalgamated with Carn Brea in 1896, but the year's balance of the joint working was seldom on the right side, owing to the low grade of the ore. On two occasions the high prices of metals brought profits, on the latter occasion arsenic helping notably. Perhaps if re-arrangements of underground methods had been instituted in early days, better results might have been obtained, but the prospects were never sufficiently promising to attract the necessary large supplies of capital. High costs and low metal prices have lately combined to create a serious adverse balance. So the mine is shut down and the lease is to be surrendered on June 30. At the meeting of shareholders held on April 26, Mr. James Wickett, the chairman, said Tincroft was the only mine with which he was connected that had given him worry, but he was grateful for the profits that had been earned many decades ago, for they had contributed

largely to his father's income and had brought many substantial and enduring advantages to the family. The chapter on Tincroft should not be finally closed without recognition of the services of the owner of the royalties, Lord Clifden, and his agent, Mr. John Gilbert, in helping to keep the mine alive during recent years.

Canada.—It is reported that the W. B. Thompson group have abandoned their option on the Flin-Flon copper mine, near The Pas, Manitoba. Previously Messrs. Hayden, Stone & Co., of Boston, had dropped their option after full examination. It is now stated that the Mining Corporation of Canada, which was associated with the W. B. Thompson option, is negotiating for an option on its own account. As readers of the report contained in last month's MAGAZINE are aware, the ore-body though large is of low grade, and the metallurgical problem is not of the simplest.

United States.—The quarrel between Mr. Karl Eilers and the Guggenheims over the control of the American Smelting & Refining Company has ended in a victory for the Guggenheims, who, however, have thought it politic to elect to the board several representatives of outside financial interests, instead of confining the directorate to their own immediate entourage. Among the directors elected in this way are representatives of the Guaranty Trust, the Royal Bank of Canada, and the Irving National Bank. The Guggenheims held 682,223 proxies, and Mr. Eilers 202,479. Mr. Eilers is the son of the late Mr. Anton Eilers, and like his father was concerned in the metallurgical management; but he has also a large financial interest. During the last year or two he has protested against some points in the Guggenheim methods, and has sought to force their hands. A year ago the Guggenheims were able to veto his re-election to the board, and his connection with the company then ceased. His grievance, to put it briefly, is that the Guggenheims, though they hold the control, have parted with most of their shares, and that they have used the "A. S. & R." for their own purposes in the stock market. Thus it is alleged that the company has been left with unprofitable smelting contracts, while the Guggenheims have benefited by the rise in the shares of the companies with whom the contracts were made. At this distance it is impossible to examine into the intricacies of what is, after all, only a personal dispute.

The output of quicksilver in the United States during 1920 is estimated at 13,070 flasks of 75 lb. each, compared with 21,348 flasks in 1919. The chief producing states were California with 9,366 flasks, and Texas with 3,601 flasks. The decline in prices was even more marked, the figure falling from the maximum, $102 per flask, in April to $49 in December.

Ecuador. — The Anglo-Ecuadorian Oilfields, Ltd., was formed two years ago to acquire the whole of the Ecuadorian property of Lobitos Oilfields, which itself operates in Peru. News was received last month that oil had been struck in the first well at a depth of 2,543 ft. The flow and oil are reported to have much the same characteristics as those of the wells operated by the Lobitos company.

Roumania.—The Roumanian Consolidated Oilfields, Ltd., is issuing £100,000 debentures to provide funds chiefly for the completion of the new refinery. The share capital of the company is being concurrently increased so that conversion rights may be given to debenture-holders. It will be remembered that the Appeal Court dismissed the claim of the company for compensation for the destruction of the oil-wells and plant during the German advance, holding that the claim should be lodged with the Roumanian Government. The British and French Governments have since agreed to pay £300,000 as their contribution, and they may increase this amount under the guarantee to the Roumanian Government. The total bill for damage is now estimated at about £1,000,000. The company has issued a circular giving an account of the present position. Since the armistice all the surface works have been re-erected, 20,000 tons of tank capacity has been constructed, and 130 kilometres of pipe-line has been relaid. The new refinery has double the capacity of that destroyed. There are now seventeen producing wells and twelve wells in course of drilling. The output since the resumption of operations has been 40,000 tons. It is hoped that the pre-war rate of output will be reached by the end of the year, and that by means of the new drilling campaign this rate will be doubled in the near future.

The production of oil in Roumania during 1920 was 1,031,030 tons, an increase of 200,000 tons over 1919, and comparing with 1,700,000 tons before the war.

Spitsbergen.—The Northern Exploration Company has offered £150,000 Secured Notes to shareholders, with the object of keeping this organization alive, and in particular of developing certain coal deposits on the east coast. These notes carry 8% interest, and are redeemable at 25% premium at the end of three years. The directors will not go to allotment unless £50,000 is subscribed. At the time of writing the result of this offer is not known.

NOTES ON OPEN-CUT MINING.

By R. S. BOTSFORD, A.R.S.M., M.Inst.M.M.

The Author discusses some recent advances in practice in open-cut mining.

OWING to the high cost of labour the close study of the economics of open-cut mining by means of steam shovel has become a necessity. Some points are considered in this paper, and particulars are given of certain experience and methods of working, particularly in connection with stripping overburden and mining iron ore and coal.

Open-Cut Iron Mining.

When the dipper of the largest stripping shovel is pulling up through the bank, there is a pull of over 40 tons concentrated in the cutting edges of the teeth, and there are few moderately hard materials that can withstand it. With hard clays and shales, it is a question of calculation whether the added cost of explosive and drilling as a preliminary preparation to loosen the ground is worth the increased capacity thereby attained as against greater wear on the machine. For example, stripping heavy clay in the Mesabi Iron Range in Minnesota cost, without blasting, 30 cents per yard, and was very hard on the shovel. However, explosives cost 39 cents per pound, of which $\frac{3}{4}$ lb. per yard would be necessary, so that it was better to change the teeth of the dipper every day to have them sharpened and to avoid blasting. When blasting is required it is not necessary to break the rock up anything like so small as is required for hand labour. It is very difficult always to have empty wagons at the shovel ready to be loaded. Most delays are caused by waiting for empty wagons. Equally important with the actual stripping operation is the management of the dump, for time can be lost there just as well as in the open-cut, and without wagons the operations cease, although costs and overhead charges continue.

During the summer of 1919, A. Guthrie & Co., working on a stripping contract close to Coleraine in the Iron Range, at the Danube pit, got a record of 231,000 yards in the month for their Model 300 shovel and a record of 357 cars per 10-hour shift using 16-yard air-dump cars. On account of the greater capacity obtained with their equipment it cost them about 20 cents per yard instead of 30 cents per yard. Moreover, they averaged 317 cars in the day shift and 318 at night, and the cars averaged $17\frac{1}{2}$ yards bank measurement. From observation I attribute their record to good management and attention to essential details. From experience they endeavour to standardize their operations, and have come down to the 16-yard Columbus car (air-dump) because they find that there is only 25% of the upkeep or repair in comparison with the larger 20-yard car. The locomotive they favour, after 3 or 4 years' experiment, is the Baldwin "Switcher type," which weighs 78 tons.

The use of the large revolving stripping shovel has permitted the development of a special kind of cut of which they take advantage, materially modifying the working conditions. (See Fig. 1).

Arrangements are made for loading on both sides of the cut, with track on either side communicating with the dump, so that loading goes on continuously, and at 35 to 40 ft. above the working floor. The cut is over 100 ft. wide at the working floor and exceeds 160 ft. wide at the top at the level of the tracks. While the shovel will deliver on tracks 200 ft. apart, it is well to have about 10 ft. excess reach in case of any spill on the track which the dipper can push off, or in case a car gets derailed, when assistance can be given to the train crew.

The next cut is taken alongside the first, but leaving the loading track in position between the two cuts, and the new cut has two loading tracks, one each side as before.

When descending to the next horizon, 35 ft. lower, the shovel digs right under one of the loading tracks, as it is preparing to do in the photograph, with a new loading track on either side, on the floors of the earlier cuts, and now takes in the ground including that supporting the track right up to the surface, and loading on to the tracks 35 ft. from the surface, whence it is hauled out on a $2\frac{1}{2}$% slope (see Fig. 2). This is done from a depth of approximately 70 ft. The section of the working cut is so large that it is only necessary to move up about once a day. One of the great advantages is that the trains are hauled out on the level until the 70 ft. horizon is started, and then only from a depth of 35 ft. The substitution of one large stripping shovel in place of standard railroad shovels reduced the pay-roll by 150 men, mostly in train crews and labour moving tracks as well as locomotives. The $2\frac{1}{2}$% slope is important and must not be exceed-

FIG. 1. THE DANUBE IRON-ORE PIT, COLERAINE, MINNESOTA.

ed even for a short distance, or fewer cars can be carried in the train. If less than $2\frac{1}{2}\%$, then a longer approach is required. Much less train equipment is required by this method in comparison with the standard railroad-type shovel loading on a track alongside, for a given depth. The number of cuts and consequent shifting of tracks and operations is a mere fraction of the ordinary method with the standard shovel, and a great deal of money is saved.

FIG. 2. LARGE STRIPPING SHOVEL ABOUT TO START A NEW CUT AT A LOWER HORIZON.

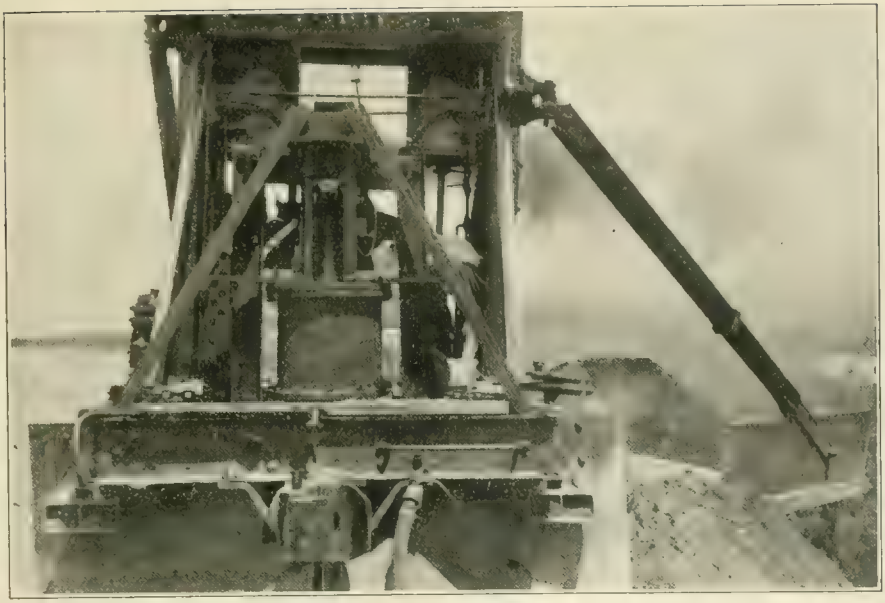

FIG 3. SPREADER IN OPERATION ON THE DUMP.

On the dump, the operations consist in dumping the train of automatic air-dump cars, operated from the locomotive, which may occupy a minute or more. Occasionally the spreader (Fig. 3) is run over the track to push the ground over the edge of the dump when necessary. Ultimately the track must be shifted, which is done in the daytime, by means of the track-shifter (Fig. 5). This moves the track out about 4 ft., and the operation goes on at about two miles an hour. Fifteen men during the day and three at night will look after the dump, whereas without the track-shifter more than three times the number would be required during the day. Thus the three machines or contrivances, (1) automatic air-dumping, (2) spreader, (3) track-shifter, do all the heavy work on the dump.

In the pit the most desirable conditions are established with a permanent approach down the centre and a run-around at the further end when this can be arranged. Where the pit is long and narrow it is necessary to use a zig-zag

FIG. 4. LARGE SHOVEL STRIPPING OVERBURDEN, AND A SMALLER SHOVEL FOLLOWING REMOVING THE COAL UNDERNEATH.

to descend to the working level. If this is on a bank which is a receding working face, there is a constant shifting of the main track as the face recedes, which closes down the work when moving the main track and is to be avoided at all costs.

In mining the comparatively soft hematite, it is first loosened with explosive and then loaded into 50-ton cars with bottom discharge. Here conditions are different, as a regular grade of ore must be maintained for shipment, and different parts are worked according to the grade called for. For this reason the smaller but equally powerful railroad-type shovel is used, as it can be easily moved around on the standard gauge track. Further, there is not so much capital tied up when one is laid off for two or three weeks.

There are approximately 200 steam shovels working in the Iron Range, the greatest iron-field in the world.

The Hull Rust pit is about 185 ft. deep, one mile across, and one and a half miles long. It is the biggest artificial hole in the world, and usually too full of smoke to obtain a good photograph. It is more than probable that the bigger operations here will be carried on with electric power, as great economy would result. For this reason due consideration should be given in laying out a new property to the desirability or otherwise of using electric power in the first instance. At the Hull Rust pit the overburden is about 100 ft. thick, and where there is a proportion of 3 of ore to 1 of overburden the ground is reserved for steam-shovel mining, and therefore unavailable for dumps, instead of underground mining which is also being carried on. A slope of about 1 to 1 is arranged for from the side lines of the property, and a berm or bare space above the ore of 20 or more feet in width to avoid having the downwash from rain carrying overburden on to the ore.

Stripping Coal by Overcasting.

Much of the expense connected with steam-shovel mining may be eliminated where conditions are similar to those encountered by Robert Holmes, at Danville, Illinois. Over a large part of the state there is a bed of coal too close to the surface to be mined by underground methods, and until he developed the present method, stripping was too expensive. The nearly horizontal layer of coal is covered with approximately 30 ft. of overburden which can be excavated with a shovel (Fig. 4). Briefly he develops a long working face along which the large revolving stripping shovel operates, digging the overburden and casting it back to the extreme reach of the shovel, uncovering the coal and disposing of the overburden in one operation. As the shovel advances along the trench it is followed by a smaller shovel which digs up the coal. The coal is removed along the trench on a narrow gauge track, so that when the large stripping shovel returns digging along the cut there is a fresh strip from which the coal has been removed for the disposal of the overburden.

Under the conditions of labour at Danville, it would be impossible to dig out this overburden and remove it in cars for less than 20 cents per yard. Digging and casting back to the final resting place is accomplished for 9 cents per yard. There is, for example, no expense for trains and dump, nor diminished capacity due to delays for empty cars. The only delay is at the end of the cut, at long intervals, required for the removal of the coal right up to the shovel before returning. This may amount to four days more or less, depending on how near the coal-removing operations have kept up to the shovel. Other conditions being satisfactory, it would be all right to mine *two* layers of coal or other material, with a few feet of dirt between, casting back the layer of valueless material between the two layers of coal before the large stripping shovel returned.

With a fixed price of \$3·75 per ton of coal delivered in the railroad cars at Danville workings, a satisfactory ratio of 1 of coal to 6 of overburden could be mined with big profits when many underground mines were closing down, for the cost was about \$1·00 per ton of coal. The cost of mining is absurdly small in comparison with underground mining or removing the material to a dump, and the profits proportionately large. It would not be worth while stripping such a low-priced product as coal, less than approximately 4 ft. thick. The limit of overburden at the rate of not more than 6 to 1 at Danville depends on the limit of the machine, which has a 90 ft. boom. Plans are ready for one with a 125 ft. boom. Naturally the thickness of bed of valuable material (coal in this instance) affects the height of material cast back, as a thicker bed on which the stripping shovel runs, after removal, leaves more room for disposal of the overburden, without the latter getting too high for the stripping shovel. With 8 ft. of coal, about 45 ft. of overburden would be the limit with a Model 300, which is the largest machine. It can propel itself over the surface of the coal on its tracks to a limit of about 20° slope, which is approached in the undulations of the coal bed. Many engineers

will recollect within their experience places where such stripping methods are applicable, in iron ore for example. Four thousand five hundred yards in a 10-hour shift as an average would be a reasonably moderate output to expect from such a large stripping shovel with an 8-yard dipper, and it is easily exceeded to the extent of 50% or more depending on the operator. Not being dependent on cars, or strikes, a good output can be maintained. The only difficulty they had at any time was to get railroad cars to take their product away, their output being considerable with several stripping shovels. The expense of operation depends, in stripping, on the cost of power and labour and conditions in the particular part of the world where the operations would be carried out, and almost anywhere would be less than those indicated, in some places a mere fraction.

In these coal-stripping operations there is not much to choose between electric shovels and steam shovels. Both are used. Where there is no electric power plant or power available, then the advantage is with the coal which is at hand for firing.

In cold weather, special precautions must be taken to keep the feed-water pipe-line from freezing, fires being built around it at intervals. A less number of men are required on the electric shovel, there is no attendant or expense of banked fires when shut-down at night, and there are no ashes or water dropped from the electric shovel as from the steam shovel, which must be cleaned up before mining the coal. The water, of course, forms ice in winter which must be dug up and removed.

Coal stripping by overcasting is a live proposition, and is taken up wherever suitable properties and equipment can be brought together under favourable conditions.

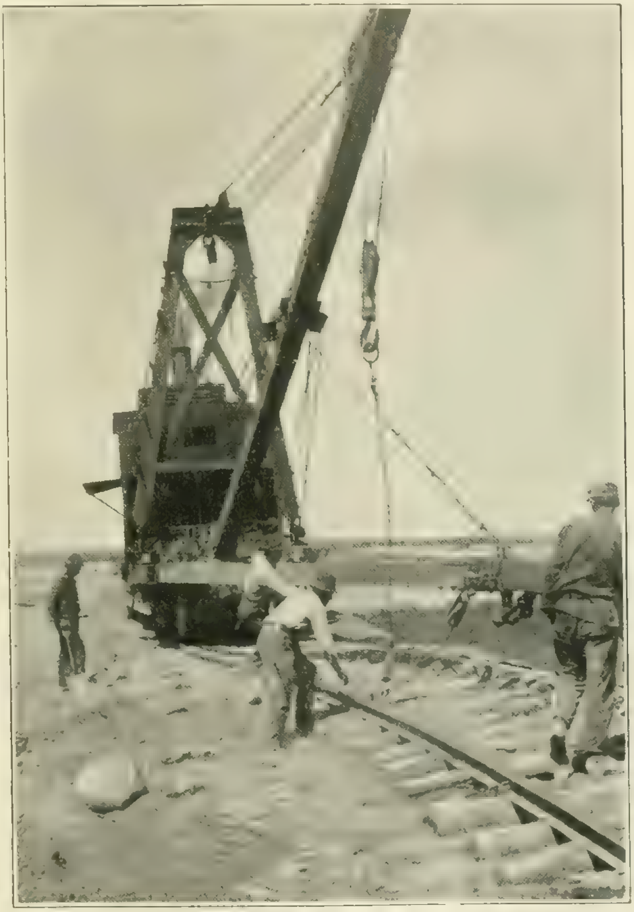

Fig. 5. Track-Shifter in Operation.

THE ORIGIN OF PRIMARY ORE DEPOSITS.

By J. D. KENDALL.

The Author contributes to the discussion on Dr. J. Morrow Campbell's recent paper on this subject.

IN the November issue of the MAGAZINE there appeared an abstract of a paper with the above title, read before the Institution of Mining and Metallurgy by Dr. J. Morrow Campbell, which interested me so much that I obtained a copy of the paper, and having read it ask to be allowed to submit a few observations thereon.

The paper contains so much that invites criticism that it would require more space than the original paper to deal with it fully. I shall therefore confine my remarks to such parts of it as seem to embody the author's ideas on the formation of ore-bodies.

Taking the paper as a whole I was perhaps most struck by the absence of drawings. The English language has great power, but it cannot describe with precision many of the features which must be accurately realized in investigations as to genesis. This can be much better done by accurate drawings which limit the exercise of the reader's imagination, and generally present the facts of form and position much more concisely.

A further surprise is the little that is said by way of showing how the suggestions offered succeed in explaining the well-known features of the different classes of ore-bodies.

The first item to which I should like to refer is concerned with crust-forming. Although not directly connected with ore-formation, yet the writer of the paper arrives at certain conclusions in connection therewith that form the kernel of his views as to ore-deposition. On the second page we read: "It has been the custom of geologists to assume the existence of two types of primary magma, the granitic above and the basaltic below. Others believe that the initial crust of the earth was basaltic and that a granitic magma developed beneath it. The truth is probably reached by assuming the existence of only one primeval magma of intermediate composition—dioritic or andesitic—which on differentiation yielded both the typical granitic and basaltic magmas."

That the primeval magma had an intermediate chemical composition, when considered in connection with granite and the basic plutonics, is probably true. But it seems clear from a consideration of the chemical constitution of the plutonic rocks and of that of the minerals composing them that, as the latter formed, differentiation would begin, and therefore it is not possible that the minerals in diorite could produce granite. This is evident when we look at the mineral composition of either the plutonic or volcanic rocks. Granite contains a large percentage of free silica; diorite contains much less, and then only in the variety called quartz-diorite. The same sort of argument leads to the conclusion that the basic rocks did not come from a substance having the mineral constitution of diorite. If the free silica of granite was primarily combined, what has become of the bases with which it was united? They are not found in the more basic rocks.

Differentiation of such a magma as that referred to above was probably due, in large measure if not entirely, to differences of specific gravity of the various minerals formed from the syntectic, combined with the effect of falling temperature. Those minerals having a less specific gravity than the average would rise; those that were heavier would fall. As a consequence of these opposite movements, and the interference arising from them, some portions of the minerals might and probably would be locked up in positions higher or lower than those due to their specific gravities. The falling minerals would be absorbed in the hotter syntectic below, to be again crystallized and separated from the more acid minerals. This process would be repeated again and again as zone after zone, downwards, cooled to the necessary temperature. The fusibility of the felspathic minerals is—with the exception of anorthite—inversely as their specific gravities.

On the second page, also, we are told that "solidification commenced at the surface by radiation of heat as ice does on water, but the result differed in that the solid was heavier than the liquid, therefore upon being broken up by tidal and storm movements it sank and was re-melted. This cycle of crust formation, foundering, and re-fusion, proceeded until the temperature of the silicate sea to a depth of probably several miles was considerably lowered." In writing this passage the author of the paper seems to have lost sight of the operation of differentiation, which must result in increasing basicity and specific gravity downwards, and prevent the comparatively light acid layer

formed on the surface from sinking as suggested. But apart from this theoretical difficulty it has been ascertained by Barns (United States Geological Survey, Bulletin 103) that the broken crust formed on molten diabase would not sink although heavier than the hot liquid below it. There is also the further objection that the suggested foundering and re-fusion, if the former were possible, by producing circulation would prevent the differentiation which the writer of the paper admits to have occurred.

At the foot of the third page of the paper is a paragraph more than usually laden with assumptions. Some of these assumptions are admitted; others are put forward as if acknowledged facts. We there read "that granitic magmas on solidification give off an aqueous mother-liquor. The primary crust was largely granitic, so we have to assume that it gave off a similar liquid. Such acid liquors invariably carry the bulk of the ore-minerals originally present in the granitic magma, so we must assume that large quantities of ores were ejected at the surface of the primary crust. These would be mostly tin, tungsten, gold, copper, zinc, and lead. Probably none of these ore deposits have survived. They must have been denuded and dispersed in sediments and in aqueous solutions."

The paper does not give the evidence which induces the writer of it to say that granitic magmas give off an aqueous mother-liquor. But I assume he refers to such occurrences as that at Clifton, Arizona, where the limestone for several hundred feet from the contact with granitic and dioritic porphyry has been replaced by garnet, etc. There is not, however, any conclusive evidence that changes like that—from calcareous to silicate rocks—were effected by solutions which came from the newly erupted magma. When the igneous intrusions occurred the limestone would be severely ruptured in many directions and to some distance from the heated rock. Moreover, contraction of the igneous rock in cooling would produce numerous other openings and fractures. Vadose waters charged with the necessary compounds could circulate through the passages so produced and might, in time, effect the alteration that has occurred at the several points. The circulating waters in their devious courses through the rocks might rise in part through the cooled magma and take up from them some of, or all, the silicates necessary to the metamorphism.

The great difficulty in the way of ascribing these non-metallic replacements to the action of magmatic waters is their interrupted occurrence along the contacts. In the Marble Bay copper mine, on Texada Island, British Columbia,* there is an interesting example of these so-called metamorphisms by magmatic waters. The mine is in limestone in the neighbourhood of three small outbursts of diorite-porphyry. The ore-body is about 200 ft. long, and occurs alongside a fault which is nearly at right angles to the perimeter of the largest mass of igneous rock. The mine has been opened to a depth of nearly 1,200 ft. by 13 levels mostly 100 ft. apart. A small dyke intersects the workings at a depth of 260 ft., also at 460, 560, and 660 ft. In the 760, 860, and 960 ft. levels there are several small dykes, and in the workings at 1,060 and 1,160 ft. there is a much larger intrusion, about 30 ft. wide. These dykes most probably are all branches from the main body of igneous rock, of which, however, there is no indication in the deepest working. The ore-body at the surface is only about 200 ft. from the near edge of the largest boss, and it goes down nearly plumb, so that the igneous rock must be very steep on that side. The ore is chalcopyrite and bornite, and occurs more or less interruptedly in a gangue of andradite, diopside, tremolite, actinolite, epidote, calcite, and a little quartz. Fig. 1 shows the mode in which the different minerals occur in some parts of the deposit. Fig. 2 is a section exposed at the surface, showing the manner in which the ore occurs in the andradite over a larger space than Fig. 1.

These gangue minerals traverse the limestone in a very irregular manner, but there is no indication of an increase in the extent of them toward the main igneous mass. Between the dykes seen in the workings and the limestone through which they have been forced there is frequently no indication of secondary silicate rocks. The formation of the gangue minerals has taken place at different times, as shown by Fig. 1; that of the chalcopyrite and bornite followed the andradite, etc.

If it be supposed that the solution or solutions which give rise to the replacement of the limestone exuded from the diorite-porphyry, that would not justify us in assuming that similar or other solutions were given off by the primeval acid crust, as suggested by Mr. Campbell, for the conditions in the two cases would be entirely different. In that of the igneous outbursts at Clifton and Marble Bay the fractures in the limestone would form very small means of escape for the previously confined

magmatic waters and gases, unless these fractures extended to the surface. If they did so, the outward rush of the imprisoned waters and gases would be so rapid that there would not be sufficient time to effect the replacement of much of the limestone before the escaping waters were exhausted. With the primitive crust it would be different. The enormous pressure of about 3,000 lb. per square inch, due to the overlying hydrosphere, would prevent any escape of occluded water with its supposed load of metallic and non-metallic minerals.

If, however, such an aqueous, silicious effusion as is suggested by the paper were to be admitted, we should still be confronted by the difficulty of explaining why, according to the supposition, some of the metals, which form an important part of the earth's crust, were subjected to magmatic differentiation, while others, more likely to so act, behaved in an entirely opposite manner. Mr. Campbell seems to have assumed what, in justice to his own ideas, requires complete demonstration.

If the exudation of magmatic waters be considered probable from both the primeval crust and the much more recent rocks referred to at Clifton and elsewhere, there is not any evidence that they were laden with metallic minerals and that the deposition of those minerals, from the latter, formed the respective ore-bodies. In each case, so far as my experience goes, the deposition of minerals was a later event.

Under the heading "Primary Ores" the following occurs in Mr. Campbell's paper: "Primary ores may be defined as those which are derived directly from rock magmas or magmatic liquids." Seeing that the formation of ore-bodies by magmatic liquids is a very debatable subject, it is surely a poor foundation on which to build an important definition. Moreover, it is likely to lead to confusion, the word "primary" having already been applied to syngenetic ores, a definition which is as unsatisfactory as Mr. Campbell's, because it is very doubtful whether any workable ore-bodies are syngenetic if we except the few and unimportant magmatic concentrations described by Vogt at Taberg, etc. The difference between primary and secondary ores is well understood in practice, the latter having been derived from the former. Such being the case it seems to me sufficient to say that "a primary ore is an ore which has not been derived from any other ore." In saying that, there is not any doubtful genetic assertion or implication.

Under the heading "Base Metals" Mr. Campbell writes: "With primary ores of copper, zinc, lead, and antimony, we are faced with the same fact that in the veins along with them quartz is almost always present. There is good reason for believing that the sulphides of these metals came up from magmas in silicic-acid solutions." It would have been much more satisfactory if that reason had been given. As regards the assertion that quartz is almost always present with deposits of base-metal minerals, it seems to me that such an indefinite statement has no ascertained bearing on the genesis of such ore-bodies. Bearing in mind that oxygen and silicon are the two most abundant elements known in the earth's crust, it is to be expected that quartz would have a wide distribution. My experience has been that in ore-bodies occurring in silicate rocks it is almost invariably the most abundant gangue mineral, but in those contained in calcareous rocks its proportion is usually small and often almost nil. Why on Mr. Campbell's supposition should there be this difference?

It would have been useful and interesting if Mr. Campbell had shown how the silicic acid solution produced the many replacement deposits that occur in different parts of the world. I need only mention a few to emphasize the importance and necessity of such a demonstration. Just now I am thinking of the silver-lead deposits at Leadville in Colorado, and of Eureka in Nevada, and also of the copper deposits of Clifton and Bisbee in Arizona. To me it seems an utter impossibility that those deposits and scores of others like them could have been formed in the way suggested in the paper. There could not have been any cavernous spaces into which the silicic acid solution could have dropped its load of metallic minerals as I have shown elsewhere.* Nor could the order in which the different minerals were deposited be accounted for.

As regards the upward succession of ore-minerals, on this part of the subject we read that it is intended to "deal only with ore-minerals occurring in veins deposited therein directly by magmatic solutions, and we may assume them to be carried in silicic acid. We also assume that an open fissure exists, up which solutions pass. After the first inrush the flow of ore-bearing liquid in the fissure is probably slow and at all parts its temperature is a little higher than that of the walls, heat being transferred from the former to the latter. ... The liquid on leaving the batholith carries say tin oxide and chalcopyrite in solution, its temperature falls as it passes upwards, and at a certain point cassiterite commences to deposit

* The Formation of Ore-bodies. Transactions Canadian Mining Institute Vol. xxi., 1918.

and continues to do so upward until all the tin in solution is exhausted. This will take place when the liquid has fallen to a temperature at which it can no longer hold tin in solution.... The same liquid carries chalcopyrite and iron bisulphide as well.... No chalcopyrite was deposited with cassiterite below, but near its upper limit chalcopyrite commences to develop and continues until a point is reached where the temperature of the liquid no longer permits it to hold copper in solution. Here again we have a range of temperature within which chalcopyrite deposits; the hotter limit is nearly coincident with the cooler limit for tin, the two may overlap slightly." This process, I submit, does not explain the cases in Cornwall where tin is found in granite and copper in slate, and it fails most strikingly in that remarkable case mentioned by Henwood† at the Botallack mine in West Cornwall, where a vein passes three times from granite to slate and in each case contains tin ore only in the former and copper ore only in the latter. Nor does it satisfy our desire to know why in the lead veins of Alston, Allendale, and Weardale the galena has been deposited principally in the calcareous beds of the Yoredales. Nor why the copper veins of Butte, Montana, are ore-bearing chiefly in the granite and almost barren in the aplite as shown in Fig. 3.

Fig. 12 A-Serpentine, B-Diabase C Quartz.

The gold veins of California, like the Beckman and Canada Hill veins, cannot possibly be filled fissures. The former has a dip of only $7\frac{1}{2}$ degrees from horizontal and the latter only 20 degrees. It is to me quite inconceivable

† Metalliferous Deposits of Cornwall and Devon, 1843.

that the hanging-wall rock of either of these veins could have been lifted in such a way, and for sufficient time, as to allow the opening to be filled with a body of quartz. The Canada Hill vein is in places 15 and 18 inches wide, although at other parts it is only a very thin seam. Many other such cases might be mentioned.

The filled-fissure suggestion fails also to show why the pitch of ore-shoots, in veins, is so often parallel to the strata of the adjoining rocks. Indeed it fails to explain all the more important features bearing on genesis, as I will endeavour to show.

space now occupied by the ore-body was not produced by the drawing apart of the rocks after being fractured.

At Wheal Alfred, near Gwinear, Cornwall,* the tin vein shown in Fig. 7 was 6 to 9 ft. wide in the slate above the elvan, increasing in the latter to 25 ft., but decreasing in the slate below to 10 ft. The elvan is about 300 ft. thick. A similar widening occurred on the tin vein, at the 100 fathom level, of the Huel Lovell mine,† in the parish of Wendron, Cornwall, as shown in Fig. 8.

The occurrence of horses in veins, like that

Fig 15. A= Skiddaw Slate B = Quartz

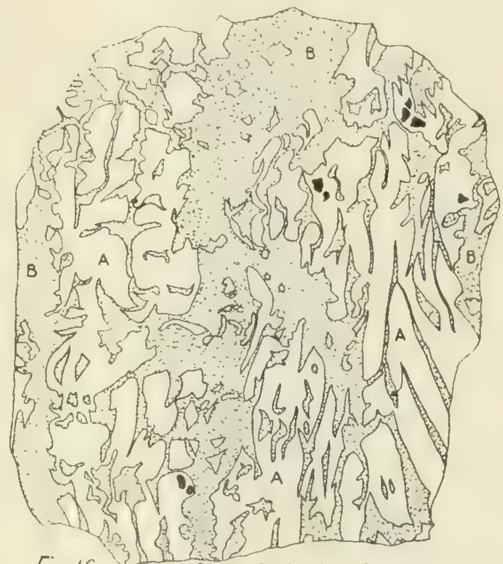

Fig 16 A = Quartz B = Ash rock ◆ = Chalcopyrite

The assumption of fractures opening wide enough to be immediately filled by either silicious or other solutions has soon to be abandoned when we look at the cross-sections of any well-defined veins. Whether an earth-fracture be straight or crooked the two sides, when drawn apart, will in nearly every case be either parallel or slightly converging when seen in vertical section, as shown by *a*, *b*, *c*, Fig. 4. Experience of veins soon shows us that they do not occur in these simple forms, in which the walls are parallel or nearly so, but that they vary in width very irregularly, as shown by the cross-sections *d*, *e*, *f*, in Fig. 5. It is quite impossible for fractures, either simple or compound, to produce openings in rocks having forms like those in Fig. 5. This difficulty is very clearly realized when we look at a cross-section like that of the upper part of the Broken Hill silver-lead deposit, as shown in Fig. 6. It does not require much thought to satisfy one that the

shown in Fig. 9, cannot result from any kind of fracture, the total width of the veins on the two sides of the horse being greater than the width either immediately above or below, that is, at *a*, *b*.

The lead-bearing veins in the Yoredales of Cumberland, Durham, and Northumberland are much wider in the limestones than in any of the shales or sandstones alternating with the limestones. An extreme case of that kind is provided by the "flats" which are found in connection with the Great and other limestones at Alston Moor. A section of one of these flats projecting from a vein is shown in Fig. 10. It is inconceivable that the filling of any kind of fracture could have produced the ore-body shown in this section.

Hundreds of such examples of the *form* of veins might be added in opposition to the filled-

* Geology of Cornwall and Devon, 1839, Sir H. de la Beche.
† Trans. Roy. Geol. Soc. of Cornwall, vol. ix., p. 167.

fissure idea, but I will now refer to a few sections exhibiting the *inner nature* of veins of different kinds. Fig. 11 is a cross-section, in the 900 ft. level, of the Pittsburgh gold vein, in Nevada City district, California. The rock in which it occurs is diabase. The various bodies of quartz forming the vein cannot be filled-fissures. Particularly can this be said of a, b, and c.

Other cross-sections of vein are given in Figs. 12, 13, and 14. Fig. 12 is a cross-section of the Maryland vein, Grass Valley, California. Fig. 13 is a horizontal section of part of the Poorman gold vein, near Nelson, British Columbia. Fig. 14 is a cross-section of the Alamo silver-lead vein, in the Slocan, British Columbia. All these sections are quite irreconcilable with Mr. Campbell's ideas, and such sections might be multiplied to any extent.

I will conclude these observations by reference to two most interesting sections of vein-rock*. Fig. 15 is from the Yewthwaite lead mine near Keswick, Cumberland, and Fig. 16 from the Bonsor vein of the Coniston mine, Lancashire. The complicated mixture of quartz and country rock in these sections shuts out, at once, any suggestion of filled-fissures, while the gradation from silicate rock to pure quartz which occurs in many places is suggestive of the quartz having originated in a manner quite different from that advocated by Mr. Campbell's paper, and which is dealt with in the "Formation of Ore-bodies" by the present writer.

*Mineral Veins of the Lake District, by J. D. Kendall. Transactions Manchester Geological Society, 1884.

BRITISH PETROGRAPHIC NOMENCLATURE.

A summary is here given of the Report of the Joint Committee of the Geological and Mineralogical Societies on the standardization of petrological terms.

In February, 1920, the Geological Society and the Mineralogical Society appointed a joint committee whose functions were to consider whether any standardization of British petrographic nomenclature is possible and desirable, and if so to make recommendations with that end in view. The chairman of the committee is Professor W. W. Watts, and the other members are Dr. J. V. Elsden, Dr. J. S. Flett, Sir Jethro Teall, Dr. H. H. Thomas, Mr. G. W. Tyrrell, appointed by the Geological Society; and Dr. J. W. Evans, Dr. F. H. Hatch, Dr. Arthur Holmes, Dr. G. T. Prior, Dr. R. H. Rastall, and Mr. W. Campbell Smith (Honorary Secretary), appointed by the Mineralogical Society.

The report of this committee has now been issued, and we give herewith a general summary of the recommendations. It is to be noted that no names have been dealt with by the committee that have general undisputed definitions, and that only British nomenclature has come within the scope of the committee. A summary of the report is given herewith, and readers who wish for the complete report should apply for copies thereof from the secretary of the committee or from the secretary of the Geological or Mineralogical Society.

Definitions Recommended.

AMPHIBOLITE is retained for unfoliated or slightly foliated metamorphic rocks of doubtful, or other than igneous, origin. It is composed essentially of hornblende and felspar, often containing various accessories, such as epidote and garnet. EPIDIORITE is retained for unfoliated metamorphosed igneous rocks of doleritic or basaltic composition in which augite has been replaced by hornblende. It usually occurs as dykes and sills. HORNBLENDE-SCHIST is distinguished from amphibolite and epidiorite by the possession of foliated texture.

ANORTHOSITE is retained in the sense of rocks similar in texture to the gabbros and composed almost entirely of basic plagioclase and almost free from ferromagnesian materials.

APLITE and PEGMATITE, when used alone as rock-names, should be used in the sense defined in Harker's Petrology for Students, 1919, pp. 38 and 39, as follows: APLITE "occurs as veins in granite. . . . It is a fine-textured rock with panidiomorphic to granulitic structure, and is somewhat more acid than the associated granite. A characteristic type occurs in connection with the muscovite-granites near Dublin. It consists of microcline, with some oligoclase, quartz, muscovite, and red garnet." PEGMATITES "consist essentially of microcline or orthoclase and quartz, often with white mica and sometimes red garnet. The texture is often extremely coarse, and there is a frequent tendency to the graphic structure." The possession of graphic structure by a pegmatite is not essential. These terms (APLITE and PEGMATITE) may be extended to rocks bearing the same relation to syenite, diorite, &c., as aplite

and pegmatite bear to granite, but, if so used, some indication of their mineralogical composition should be given.

BASALT. The term used alone should not imply the presence of olivine. Basalts containing olivine as an essential constituent should be described as OLIVINE-BASALTS. No definite line is drawn between basalt and dolerite. The distinction depends on coarseness of texture.

CHARNOCKITE. The committee recommends that when reference is made to the "charnockite series" the word "series" be never omitted. Reference to this series of rocks as "the charnockites" is to be avoided. It is further recommended that charnockite as a rock-name be restricted to the granulitic variety of hypersthene-granite of the type locality as defined by Holland in 1893, and to rocks practically identical with this.

DIORITE should be limited to plutonic rocks of intermediate composition, the dominant felspar being an acid plagioclase. More basic rocks consisting of hornblende and basic plagioclase should be classed with the gabbros.

DOLERITE is retained in the sense of a coarse-grained rock of basaltic composition, usually, but not always, hypabyssal. No definite line is drawn between basalt and dolerite. The distinction depends on coarseness of texture.

ESSEXITE is retained for rocks practically identical with, or which show but slight divergence from, the original type of Salem Neck, Essex Co., Massachusetts.

FELSITE is retained for those acid and intermediate intrusives which carry no porphyritic constituent and in which the texture is felsitic.

FELSITIC may be used to designate the cryptocrystalline texture of felsites and similar rocks. The term "microfelsitic," used by certain authors, is unnecessary.

GABBRO includes plutonic rocks of basic composition consisting essentially of a basic plagioclase with one or more ferromagnesian constituents, usually a pyroxene but sometimes hornblende, and with or without olivine.

GNEISS is a medium or coarse-grained crystalline rock possessing some form of parallel structure due either to the uniform orientation of certain tabular or prismatic minerals, or to the presence of wavy discontinuous surfaces indicating a lenticular or phacoidal structure, or of bands of varying mineralogical composition which retain their continuity and parallelism throughout a considerable mass of rock (banded gneisses). Gneisses may be of igneous, sedimentary, or doubtful origin. Those of igneous origin (ortho-gneisses) may have acquired their characteristic structure before, during, or subsequent to consolidation, and only in the last-mentioned class can they be said to be metamorphic rocks. Those of sedimentary origin (para-gneisses) are invariably metamorphic rocks owing to the development in them of new minerals; their parallel structure may in some cases follow planes due to deposition, in others due to deformation. The term "gneiss," when used without qualification, should imply a rock of granitic composition but not necessarily of igneous origin.

SCHIST (crystalline schists) differs from gneiss in being of finer grain, and in possessing a well-marked tendency to split into thin layers, except when puckered or folded by movement subsequent to the development of schistosity. The term carries with it no mineralogical connotation.

GRANODIORITE is to be retained for rocks intermediate between quartz-diorite and granite in which orthoclase, while present as a notable constituent, is always subordinate in amount to the plagioclase.

GRANOPHYRE is retained in the sense in which the term is used by Rosenbusch (1872), and by Harker.

GRANULITE is not to be used in the sense of Michael Lévy, for muscovite-granite. When used as a rock-name it should be used only for rocks with granulitic texture, and should be qualified by prefixing the name of the mineral, or minerals, which characterize the rock.

GRANULITIC texture may be used for that texture of rocks characterized by even-sized and closely-fitting grains. It is applicable to metamorphosed sedimentary and metamorphosed igneous rocks, and, to a more limited extent, to igneous rocks in which the texture has been produced directly. The texture shown in Pl. 46, fig. 1, of Mem. Geol. Surv. Gt. Brit., 1907, N.W. Highlands of Scotland, is granulitic. The term granulitic should not be used to describe those textures of dolerites so described by Judd (*Q.J.G.S.*, 1886, vol. 42, pp. 68, 76 and pl. 5). For such textures granulitic should be replaced by intergranular (Evans).

KENYTE is retained for rocks practically identical with the kenytes of Mt. Kenya described by Gregory, 1900.

LAMPROPHYRE is to be retained in its present generally accepted sense to cover the "Lamprophyrische Ganggesteine" of Rosenbusch, 1910, the sense employed by Harker, Petrology for Students, 1919.

LEUCITE-PHONOLITE is to be used in the

sense adopted by Zirkel (1893) for a phonolite containing leucite in addition to nepheline and alkali-felspar.

LEUCITE-TRACHYTE is to be used in the sense of vom Rath (1867), as adopted by Zirkel (1893) and by Washington (1897); that is, a volcanic rock containing leucite in addition to the constituents of trachyte, and consisting, therefore, essentially of alkali-felspar and leucite, with relatively small amounts of ferromagnesian minerals, nepheline being absent or present as a minor accessory.

LEUCO- should not be used as a prefix indicating the presence of leucite, for instance, in leucotephrite.

META-, if used as a prefix, is understood to imply alteration of the original rock-type to the name of which it is prefixed.

MICA-SYENITE is retained in the sense of a syenite with dominant mica.

MINETTE is retained in use for the igneous rocks at present so named.

MONZONITE should be restricted to rocks of the type occurring in the Monzoni district, Tyrol, typically augite-bearing and containing a noteworthy amount of basic plagioclase in addition to orthoclase. The term "monzonite series" may be used to comprehend related rocks whether more basic or more acid than monzonite itself.

NEPHELINITE, LEUCITITE, and TEPHRITE are to be retained in use in the sense at present adopted by British authors. They do not contain olivine as an essential constituent, but may contain it as an accessory. The names NEPHELINE-BASALT, LEUCITE-BASALT, and BASANITE, are used so frequently that the committee does not feel able to recommend their disuse, but it would prefer to see these terms replaced by "olivine-nephelinite," "olivine-leucitite," and "olivine-tephrite."

OBSIDIAN. Glassy volcanic rocks of acid or intermediate composition, to be distinguished when evidence of composition is available, as rhyolite-obsidian, trachyte-obsidian, phonolite-obsidian, dacite-obsidian, andesite-obsidian.

ORTHO-. The use of this prefix as an abbreviation for orthoclase or to signify that a rock is rich in that mineral is not recommended. It is retained as a prefix to the name of a metamorphic rock to indicate igneous origin.

PANTELLERITE is allowable for rocks practically identical with those of the type locality, but preferably should be replaced by soda-rhyolite [or soda-trachyte] (Pantellaria type).

PARA- is retained as a prefix to the name of a metamorphic rock to indicate sedimentary origin. The significations given to this prefix by Loewinson-Lessing (1905), and by Lacroix (1920), are not adopted.

PERIDOTITE. Holocrystalline igneous rocks of ultrabasic composition, rich in olivine, and free from felspar or containing it only as an accessory constituent. Certain olivine-rich rocks which have been described as "hornblende-picrites" should be included. Varieties should be described by prefixing the name of the mineral characterizing them. The names "dunite" and "lherzolite," being well established and clearly understood, may be retained.

PICRITE should be restricted to rocks of the type locality of Söhle, Moravia, as described by Tschermak (1866), and to those closely similar rocks associated with teschenites and theralites in other regions.

PITCHSTONE. Glassy rocks of similar range in composition to obsidian, but characterized externally by pitchy lustre, splintery or hackly fracture, and a relatively high content of water. They are usually hypabyssal.

PORPHYRITIC TEXTURE. The definition given by Teall in 1888 (*British Petrography*, p. 51) is adopted, namely: "When . . . certain constituents occur as large or more or less perfect crystals in a matrix of finer grain, the rock is said to be porphyritic."

PORPHYRY and PORPHYRITE. Hypabyssal rocks of acid or intermediate composition with one or more porphyritic constituents in a crystalline (including cryptocrystalline) groundmass. Such rocks with dominant alkali-felspar are termed "porphyry," as distinct from those with dominant soda-lime-felspar, which are termed "porphyrite." These terms should be qualified by prefixing the name of the mineral or minerals which occur as porphyritic constituents. The name "granite-porphyry" is ambiguous, and should not be used.

PYROXENITE. Those members of the perknite group with dominant pyroxene; that is, in the original sense of Coquand, and the sense in which it is employed by Harker and Hatch. Perknite, introduced by Turner (1901), and adopted by Hatch (Igneous Rocks, 1914), may be usefully employed as a group name for holocrystalline igneous rocks composed of various combinations of hornblende, augite, and rhombic pyroxenes, together with accessory biotite, olivine and iron-ores. They occur as deep-seated masses or as dykes.

SHONKINITE is retained in the sense of the original definition of Weed and Pirsson (1895), and the more detailed definition of Pirsson (1900). The rock of Square Butte, Highwood Mountains, Montana, described by Weed and

Pirsson and analysed by the latter, is an olivine-bearing shonkinite with accessory nepheline, sodalite, etc., in small quantities. If, in certain varieties of shonkinite, leucite or nepheline become notable constituents, such rocks should be distinguished as "leucite-shonkinite" or "nephelene-shonkinite."

THERALITE is retained for nephelene-gabbros, the rock adopted as the type being the theralite of Duppau, Bohemia, and not the rock originally described as theralite from Gordon's Butte, Crazy Mountains, Montana.

TONALITE should be replaced by quartz-diorite (Tonale type).

TRACHYBASALT is adopted to replace the term "trachydolerite" as used by Washington in 1897, that is, for intermediate potash-rich rocks containing basic plagioclase together with orthoclase. The use of the term trachybasalt in the sense of Boricky (1873) having been long discontinued, no confusion should arise from its re-introduction in a new and self-explanatory sense.

TRACHYTE. Tyrrell's proposal to use "trachyte," "bostonite," and "keratophyre," with textural significations for rocks which have essentially the same chemical and mineral compositions, regardless of whether they are of extrusive or intrusive origin, is not adopted.

Obsolete Words.

The following terms have been used in more than one sense, and are either obsolete or unnecessary, so it is recommended that their further use as petrological terms should be avoided: Adamellite, Anamesite, Aphanite, Bauxitite, Binary granite, Cipolin, Cornubianite, Diabase, Diallagite, Domite, Dunstone, Euphotide, Eurite, Felspar-rock, Granitite, Hyperite, Hypersthenite, Leptynolite, Leucitophyre, Leucotephrite, Melaphyre, Nepheline-dolerite, Oligoclasite, Palæopicrite, Syenitite, Trachydolerite, Wehrlite.

Synonyms.

The following is a list of synonyms, with the term printed in small capitals which is recommended in preference to the alternative term, or terms, which are printed in ordinary type.

ACCIDENTAL INCLUSION (Harker, 1900): exogenous enclosure.

ACID: persilicic.

ALLOTRIOMORPHIC (Rosenbusch, 1897): xenomorphic; anhedral.

ARENACEOUS: psammitic.

ARGILLACEOUS: pelitic; lutaceous.

BASIC: subsilicic.

COGNATE INCLUSION (Harker, 1900): autolith; endogenous enclosure.

CONTACT METAMORPHISM: exomorphism.

CORONA: REACTION RIM; kelyphitic rim. If the corona can be shown to be due to alteration or modification of the nucleus the term "reaction rim" is preferred.

GLASSY: Hyalo-; vitro-.

HEMICRYSTALLINE: merocrystalline; semicrystalline.

HYPIDIOMORPHIC: hypautomorphic; subhedral.

IDIOMORPHIC: automorphic; euhedral.

INCLUSION (in rock): enclosure; included nodule.

INTERMEDIATE (silica content): mediosilicic.

MULLION STRUCTURE (Kinahan, 1891): rodding structure.

ORBICULAR STRUCTURE (Delesse, 1849): spheroidal structure.

PILLOW STRUCTURE: ellipsoidal structure.

PSEPHITIC: rudaceous.

LETTERS TO THE EDITOR

The Greenside Mine.

The Editor:

Sir—I am afraid your correspondent "Interested" is not so conversant with the financial part of Greenside mine as he would appear to be. A profit of 14% per annum is a good thing, but I am sure if it was realized here, it was prior to the last 60 years.

I am puzzled to know what paid-up capital "Interested" based his calculations on, and how obtained, as the conversion of the partnership company to limited liability only took place in 1890. Possibly it was over-capitalized then, but as there was no public issue this mattered little to those interested.

From 1890 to 1919 the mine was under my management, and during those years we had good and bad times, and made profits with pig lead at a very low figure. But unfortunately during the whole of these 29 years, royalties, rates, and taxes practically absorbed *one half* of the gross profits. Greenside has been a wonderful mine, although a low-grade proposition. By adopting up-to-date appliances (for instance, it was the first metalliferous mine in this country to adopt electricity), it managed to exist with pig lead at £9. 6s. per ton, and silver at 1s. 10d. per oz. There are still chances of success in this old mine with fair and reasonable royalties. The owners are now prepared to modify their terms, but, unfortunately, not be-

fore the company decided on voluntary liquidation.

WM. H. BORLASE,
Liquidator and late Manager.
Greenside, Cumberland, March 24.

Wave-Transmission Rock-Drill.

The Editor:

Sir—I have read the articles in your issues of February and March on Wave-Power Transmission. I disagree altogether with Mr. Risdon's opinion as to the suitability of this system of power-transmission for rock-drilling, as I hold it to be hopelessly inefficient when judged from the power expended *on the surface*, and the number of feet actually bored per unit of time in the rock face.

Much has been written and published in recent periodicals and daily papers as to the supposed advantages to be gained by the substitution of wave-power for compressed air, but I hold that the comparisons have been most unfair to the compressed-air system. In all cases that I have noticed it seems to be assumed that electric power is to be used for driving both the wave generator and the compressor, and we are then informed that greater drilling speeds can be obtained per horse-power expended by the adoption of the wave-power system. I disagree with this representation of the case in all particulars.

If the two systems are to be compared on a fair basis, we ought to assume that one system or the other is to be installed on a mine which is about to be equipped, and due regard should be paid to the conditions which will exist when the mining operations are being carried on at a moderate depth; for the sake of argument let us say 1,000 ft., and, as I will show later on, the balance will turn more and more decidedly in favour of the compressed-air machines as greater depths are reached.

In the compressed-air system, boilers and steam-driven air-compressors will have to be erected, the compressed air being led directly to the air-drills at the working faces. If the wave-power transmission is to be installed, the steam will have to be taken to suitable high-speed engines coupled to dynamos, the high-voltage current conducted down the shaft to the chamber or chambers which have been provided for the reception of the wave generators and the requisite electric switch-gear, transformers, and motor or motors. The power pipe-line will start in these chambers and be led to the various rock-drills.

Obviously the compressed-air system is by far the simpler, being merely boilers, steam-driven air-compressor, pipe-line, and rock-drills. In the case of the wave-power system we have: boilers, high-speed steam engine, dynamo, electric cables, step-down transformers, electric motors, wave generators, pipe-line, rock-drills.

In both cases the transformation of energy and its transmission will entail unavoidable losses. Let us see what they amount to in each case, assuming that 1,000 i.h.p. is being generated on the surface. As to the compressed-air system, any good manufacturer of air-compressors will be quite prepared to guarantee 5·8 cubic feet of free air compressed to 80 lb. gauge pressure per minute per i.h.p. in the steam engine. With a suitable sized air pipe-line, the loss of pressure at a distance of 1,000 ft. will certainly not amount to more than 2 lb. per square inch, and even this amount of energy is not entirely wasted, as the volume of the air is increased proportionately with the loss of pressure. For the moment, however, we may assume that the loss is a complete loss as it simplifies the comparisons, and that we now have 5,800 cubic feet (measured as free air) at 78 lb. per sq. in. available for operating the rock-drills.

The wave-power drill manufacturers seem to have adopted for purposes of comparisons with their own machines a cradle type of air-driven rock-drill of a well-known make, and for the sake of our example we will also take a machine of this type, though we should note in passing that there are other and more efficient types of rock-drills available. The cradle type of air rock-drill mentioned above requires not more than 100 cubic feet of free air per minute (measured as free air), and many rock-drill manufacturers will be very pleased to guarantee a considerably smaller consumption. This machine will easily bore, in granite, at the rate of not less than 8 in. per minute with a bit of 1⅝ in. diameter, so that with 5,800 cubic feet (measured as free air) available, we have a boring capacity of $58 \times 8 = 464$ inches per minute.

Turning now to the wave-power transmission plant, with a 1,000 i.h.p. in the cylinders of the steam engine we shall have a brake h.p. available of about 900; this will give us at the terminals of the dynamo, assuming an efficiency of 93%, which is quite good, the equivalent of 837 h.p. The cables down the shaft will entail a further loss of 5%, and the step-down transformers will account for yet another 2% of the balance, leaving the equivalent of 779·25 h.p. available at the terminals of the electric motors which are coupled to the wave-generators.

When I saw the wave-power drill at work,

I noted that the wave generator required 12 h.p. in the motor to operate one drill, and I was informed that the drill was capable of boring in granite with a $1\frac{5}{8}$ in. diameter bit at the rate of 5 in. per minute. My own observations do not bear out the latter statement, and I am inclined to believe that the actual boring speed would not exceed one half of the amount given above. But assuming for the sake of argument that the figures are correct as stated, and that 12 h.p. delivered to the terminals of the electric motor is equivalent to a drilling speed of 5 in. per minute with a bit of the size taken, we have a total drilling capacity for 1,000 i.h.p. on the surface of 779·2 multiplied by 5 divided by 12 = 324·6 in. per minute.

Stated in another way, the drilling capacities of the two systems per minute per i.h.p. on the surface are: compressed-air system, 464 in.; wave-power drill, 324 in.

From the above considerations I hold that the wave-power system is not a serious competitor to the pneumatic, even if no other advantages accrued from the use of compressed air as a means of operating rock-drills, and when Mr. Risdon states, as he does toward the end of his article in the March issue, that manufacturers of compressed-air plant are living in anxious times from the fear of the proposed new system of running rock-drills, he is very far from the truth. I can assure him that manufacturers of compressed-air rock-drills are very anxious indeed to cut out the talk and get down to actualities, and that the sooner a reasonable-sized installation of wave-power rock-drills is in actual use for serious mining work the better they will be pleased, as they are quite convinced that its replacement by the much more efficient and simple pneumatic system is only a question of a very short time indeed.

With the wave-power rock-drill some system of ventilation of the working faces, especially in development work where the ends may be far from the main ventilation currents, will be imperative, and will add much to the overall cost of breaking the ground; with pneumatic drills, on the other hand, this is provided for by the exhaust, and the energy which was counted as lost in the air-compressor at the surface, due to the heat of compression absorbing power, now appears as refrigeration in the working places, and how important this is will be readily admitted by all actually engaged in underground drilling.

To sum up, I consider the main advantages of the pneumatic system can be placed under the following heads: Simpler installation; faster boring speeds per i.h.p. at the surface; more flexible system; ventilation of the working places; refrigeration of the working places; helps to dry the air in the working places; dry drilling can be done when required.

I assume that dry drilling is quite impossible with the wave-motion drill, and it is well known that certain deep and hot mines will not consider wet drilling for a single moment, as the humidity of the atmosphere in the working places is even now almost intolerable.

There are many other advantages to be obtained from the installation of the pneumatic system, but as they are well known to mining engineers it is needless to occupy any more of your valuable space, on which I fear I have already unduly encroached.

R. de H. St. Stephens.

Camborne, April 10.

BOOK REVIEWS

This World of Ours. By J. H. Curle. Cloth, octavo, 315 pages. Price 7s. 6d. net. London: Methuen & Co., Ltd.

I have twice read most of "This World of Ours," and many parts I have even again re-read, for I have been greatly interested. Those who imagine the opening sentence, so reminiscent of the old admonition, "Cheer up! You'll be a long time dead!" to be the forerunner of a volume of sombre colour will be agreeably disappointed, for many bright pictures will be found thereafter.

My initial attempt at reading the book was not a success, for I soon became entangled in its peculiarities of punctuation; and my preconceived notions of good writing were upset by sentences and phrases terminated by prepositions. These, coming from the pen of an experienced writer like Mr. Curle, caused me to seek for some studied effect; and I struggled manfully on, often losing the gist of the narrative in attempting to find the hidden rhythm or other intention of the author. I progressed for several pages, stumbling over such difficulties as the following sentence: "For eight hours each day, or, every third week, each night, I had the amalgam plates in trust; . . .", and finally coming to grief at the bottom of page 22 in the full belief that four horses had been sitting beside Mr. Curle in a Cape cart and that Johann Rissik held the reins and H. B. Marshall. I laid the book aside, not knowing whether I had been listening to a story told by a man with an impediment in his speech, or whether, sitting in one of a string of L.C.C. tramcars during the congested hours of traffic, I had been reading and the sentences had been punctuated

for me by frequent and sudden applications of the brake. Having fully convinced myself that the subtlety of the sentence-maker was beyond my ken, I retraced my steps, started again at the beginning and, mentally supplying an occasional semi-colon and leaving out most of the commas, I soon became enmeshed in an interest of travel that seldom flagged.

Perhaps the parts of Mr. Curle's book which least appeal to one are those in which he attacks the Christian church; and it is to be feared that much will be found in this direction which will greatly detract from the pleasure of those readers who are sensitive regarding such matters. Indeed, it is difficult to see why, because crab eats crab, and unhygienic savages at Nyanza die of sleeping sickness, Mr. Curle should revile curates and clergy, any more than one should feel moved to do so because at Verespatak the life of a lamb was sacrificed in order that Mr. Curle might fill himself to repletion and, in an ecstasy of surfeit and emotion, endeavour to embrace a fat old Hungarian girl. And oh! the conceit of the Scot who says that, he being an agnostic, all thinkers must also become agnostics!

The first chapter of the book touches lightly on the youthful days of the author, his first trip to Australia, his return via Colombo, a visit to Africa, and his subsequent University life. The next chapter sees him returned to Africa and eventually becoming managing director of an East Rand coal mine. During the 6½ years spent on the Rand the author visits Rhodesia, Kimberley, and other places. We should have liked from him, as a sordid setting for the diamond, one of his pen pictures of Kimberley, depicting its hot, dusty, depressing, and crooked streets and uninteresting surroundings. Instead, we have to be content with the usual banal remarks about the vanity of woman and the vice of man, and with the oft-repeated reference to buckets of diamonds which nearly every writer on Kimberley seems compelled to make.

Chapter three sees the author standing in reverie near the old fish-market of Cape Town on the eve of his departure from Africa; and it is in this chapter that the true writing of the book begins. In it we get a fine retrospect, a fine description of men, beasts, and places, and, by the way, some very good tips for intending sportsmen. Standing there in the still twilight in sleepy, pretty little Cape Town—so often swept by blusterous gales—the author puts into words what many a traveller must have felt: the vastness of the African continent. It is strange that this immensity of Africa should be felt at Cape Town more than at Durban, East London, or Port Elizabeth, which are also its portals. I have felt the immensity of the Asian continent more when standing under the shadow of the peaks of Hong Kong than in either Shanghai, Saigon, or Singapore. Is it that the nearby mountains or hills lend themselves to such reveries? If so, we have to thank Table Mountain for a fine descriptive chapter from Mr. Curle.

The author next takes us to India, Australia, South America, Siberia, the Gold Coast, Western North-America, and Klondyke, a very long distance to travel in 20 pages. Nevertheless, he finds space to give us a stirring description of an accident which befell his sleigh on the false ice of the Amur at 20° F. below zero. The staccato system of punctuation here suits the situation; the story has atmosphere; we are actually with the men and horses in their struggles; and we feel greatly relieved when all ends well.

Pleasure travels in Spain and the north of Africa give history as well as happy descriptions of the places visited; and so mild has become the language of this vigorous writer that he calls the odours of Harar nothing stronger than a "shocking stench."

To attempt to follow the writer through all his travels would be futile; but we are commercially interested in his Lake Guatavita, two days' ride from Bogota in South America, because we have heard recently of a resuscitated project to remove the mud from this lake and obtain the legendary jewels.

During his peregrinations round the Caribbean Sea, the author tells an amusing story against himself which threatened to become serious, while attempting to land at Aux Cayes. He later gives us a graphic description of a bull-fight in Barcelona which, like the story of the sleigh accident, is much assisted by the staccato effect of the punctuation. From journeys up and down Europe the itinerary changes to the country between Archangel and Astrachan. Among other places, Nizhni was visited and the fair found to have been destroyed, so people said, by the advent of the Siberian railway; but, as far as my recollection goes, history relates that the real splendour of Nizhni fair departed, and never returned, after the slaughter of the populace by Ivan the Terrible.

Astrachan, the great centre for caviare—the roe of the sturgeon—is visited; and the author's remarks thereon remind one of the days before the war, when caviare was displayed for sale in large tubs placed outside the fish shops in large Russian cities at ridiculously low prices.

One gets a general impression from Mr. Curle's book that he considers the women of most countries much superior to the men. Page 209 gives such an example. Here we have a song in favour of the Slav woman, to which it is doubtful whether all who have dwelt in Russia will subscribe; but, no doubt, all will heartily agree with the sentiments with which the twelfth chapter is concluded.

The descriptions of the Holy Land and of the dwellers therein are full of interest; and one cannot but be impressed by the author's oft-expressed high opinion of the Jew of to-day. An interesting interlude is a thumb-nail sketch of American tourists in the Church of the Nativity. The sketch is so thoroughly typical that one feels it to be true to the life.

The traveller then takes us through India and the Far East; but were he to revisit the latter, he would find matters in Singapore far different from those depicted on page 269. The local D.O.R.A. has cleared out all the white prostitutes from Malay Street; and the glory of Cossack Street has departed. The Japanese higher classes have also formed a strong society, backed by much money and with widely distributed branches, for inducing their frailer women-folk to depart from foreign shores and compete with their sisters in the overcrowded land of their nativity. All British dwellers in the Far East will heartily endorse the author's praise of the Chinese and his criticism of the Japanese. The latter, taking advantage of our war preoccupation, stepped into the Malay Peninsula and bought houses and rubber lands to such an extent that it became necessary to pass an enactment practically preventing the sale of real estate. So far, fortunately, he has been unable to obtain a footing in Colombo.

All will not agree with the comparison between Javanese and Malay women. Generally speaking, a loose woman of either race is very, very loose; and, not taking much account of venereal disease, is most often a being best fitted for the lazarette.

The journey next continues to the South Seas, the author taking his final leave of us at a Presbyterian mission station in the New Hebrides; those of us who have done our modicum of world's travel envy him his excellent memory and his facile pen.

So ends "This World of Ours." A little boastful, perhaps; perhaps at times a little arrogant; but greatly interesting as a book of travel, and useful to many as a book of reference.

V. F. Stanley Low.

Coal Washing. By Ernst Prochaska, M.E. Cloth, octavo, 382 pages, illustrated. Price 24s. net. New York and London: The McGraw-Hill Book Company.

The number of books devoted entirely to the cleaning of coal is so limited that the publication of a new work on the subject is of distinct importance, especially when it is, upon the whole, well done. Needless to say, it is written by an American, and is restricted to American practice, but it is idle to deny that it would have been better had its Americanism not been so pronounced. The author appears to have very little knowledge either of British literature or of British practice in his subject, and it is somewhat amusing to find him writing of appliances as used "in Europe," without any appreciation of the very wide difference that exists between British and Continental coal-washing methods. On the other hand there is much that we on this side can learn from American practice as described by Mr. Prochaska, and attention may be directed particularly to his insistence upon the use of automatic feeding devices for regulating the supply of coal to the washers, and of automatic sampling appliances for taking regular samples of the various products, two items in which we are decidedly deficient in this country.

The book is divided into two parts, the first dealing with the history and development of coal washing, and the second with details of the various methods and appliances as they are used to-day. In the former his imperfect knowledge of the British literature of the subject is a drawback; for example, he does not seem to know that the first jig with fixed sieve was devised by a Cornishman, Captain Petherick, about the year 1830. Again, his statement that the jig "has finally attained its present position as the only successful apparatus for washing coal" is far too sweeping; in this country we have numbers of other appliances doing quite satisfactory work. The author entirely ignores the shaking table as used for washing nut coal, such as the Campbell and Craig tables, and more recently the Notanos washer of Messrs. Head, Wrightson & Co., Ltd., all of which are well known in this country; on the other hand we have much to learn in the use of tables of Wilfley type, which are being used in America for washing fine coal, and to which the author devotes a very instructive chapter.

There are also valuable chapters dealing with the economic aspect of the question, and these demonstrate that the author really knows better than his opening chapter would lead one

to suppose, as he concludes this with a "maxim" to the effect that the object of the preparation of coal is to "secure a maximum price per ton of output." Needless to say, this is quite false; the real object is to secure the maximum *profit* per ton of mine output, and no one knows this better than the author himself.

HENRY LOUIS.

Political and Commercial Geology. Edited by J. E. SPURR. Cloth, octavo, 570 pages, illustrated. Price 30s. New York and London: McGraw-Hill Company.

This book deals with the raw materials of the metal industry and commerce, principally, if not wholly, with those which during the war came under Government control; it concerns itself with their sources, their markets, and their places of consumption.

Each raw material is handled separately by a specialist, such specialist being generally the one into whose hands, under the Bureau of Mines in the United States, watch over the particular material was entrusted for war purposes. The whole series is shortly introduced by J. E. Spurr—now editor of the *Engineering and Mining Journal* of New York, but during the war Chief of the Mineral Boards—who at the end more comprehensively summarizes the position disclosed.

The attention each material receives begins with its uses, and then proceeds with the practice by which it is made marketable; the chances and effects of possible changes in practice; the part, essential or luxurious, replaceable or irreplaceable, the particular material plays; the respective geographical and geological distributions; the territorial productions; and the parts taken by the several nations in the final control. All these aspects are under separate headings, the salient features being assembled in a useful summary.

Thus are treated in succession: petroleum; coal; iron; manganese; chromium; nickel; tungsten; vanadium; antimony; molybdenum; radium and uranium; zirconium, monazite, thorium, and mesothorium; copper; lead; zinc; tin; mercury; bauxite and aluminium; emery and corundum; magnesite; graphite; asbestos; phosphate; potash; nitrogen; pyrite and sulphur; gold; silver; and platinum. Assembling these under a broad classification, fuels occupy about 50 pages; iron and steel 40 pages; the ferro-alloy metals 90 pages; the rare metals and earths 30 pages; the major base metals 110 pages; the minor metals 60 pages; and the precious metals 60 pages. To these, in conclusion, are added about 25 pages wherein the editor puts and answers the question "Who owns the earth?"

The declared purpose of this series is to shed light upon the vast political significance of commercial control of mineral wealth. It abundantly succeeds. The actual fact of this importance was painfully realized during the war, but the forces at work, unfelt though compelling, were not so apparent. They are here traced and recorded. In some commodities, coal and iron for instance, territorial or national control is adequate; the material generally need not be taken away to be made marketable. In others, zinc and nickel for instance, control is effected largely through smelters and refineries and through selling contracts, the materials being of sufficient value to bear the burden of freights. Control with these is possible without mine-ownership, and may become foreign, the raw materials passing to other countries to be converted.

War showed Germany largely controlling the metal industries, and the Allies in consequence with an incomplete equipment for the test of war. It showed, moreover, that though a foreign interest could by war be eliminated, it left the national industry with much to improvise. In laying these things bare, the book pictures the movements of ores to works, and of metals to and from their markets, a broad and interesting view. It casts glimpses into the future, as when it envisages the ultimate transference of the balance of power to the Pacific by reason of the immense coal resources of China. These aspects are of particular importance to the political economist, but at the same time they cannot fail to interest the mining engineer. In addition, for the latter the details of occurrence, use, practice, etc., will be found neatly yet comprehensively summarized.

With many contributors styles differ, but the writing is often excellent, clear, informative, and precise. Sometimes it is a little biased, as when it imputes an aggressive nationalistic policy to Britain; while throughout it shows concern for the still stronger nationalism of Japan; Germany it regards as punished for pressing nationalism too far. The whole book must, however, be regarded as a very valuable contribution to industrial literature, and one deserving of wide circulation. The net proceeds of its sale will be used to further the purpose to which it is itself devoted.

The United States and the British Empire cannot but feel flattered by the place they take in the world's mineral industry, these two States largely owning that industry.

S. J. TRUSCOTT.

Lubricating and Allied Oils. By ELLIOTT A. EVANS, F.C.S., A.M.I.P.T. Cloth, octavo, 144 pages, illustrated. Price 9s. 6d. net. London: Chapman & Hall, Ltd., 11, Henrietta Street, W.C.2.

The "Directly-Useful Technical Series" of books published by Messrs. Chapman & Hall, Ltd., has recently been added to by the production of the present little volume on lubricants, which should prove of some practical use to oil technologists in the course of their chemical work in the laboratory, and to engineers and others who may constantly have to investigate the properties of oils suitable to their several requirements. The book, however, is remarkable for the unfortunate admixture of relevant and irrelevant matter (the "directly useful and the indirectly useful"), and in view of its essentially practical purport, we are frankly surprised at some of the chapters and paragraphs which the author has seen fit to include in the text.

The direct utility of the volume, in our opinion, centres chiefly in Chapters 4, 5, and 6, which discuss the physical and chemical tests usually applied to lubricating and allied oils; this section is undoubtedly good because, although largely descriptive of well-known standard methods, the author has supplemented these with many pertinent hints on their manipulation, drawn from his own practical experience. In this connection we would mention particularly his remarks on flash-point determination, in which he summarizes the commoner sources of error possible under varying conditions of operation, and he adduces some most interesting results of experiments made personally showing, among other things, how the flash-point varies with the rate of heating and with the time intervals taken for inserting the flame. Viscosity also receives excellent treatment, and the Redwood, Engler, and Saybolt viscometers are fully discussed, while the conversion tables included for these types are most useful as a means of rapid comparison between the conventional expressions used in each case. The chemical tests are lucidly described and include all those determinations usually made for ordinary purposes; in the paragraphs dealing with sulphur estimation no mention is made of Jackson and Richardson's modified form of apparatus for the lamp method, described in a paper read before the Institution of Petroleum Technologists in November last, which would seem to offer decided advantages over the better known Esling apparatus. (See *Journal* of Inst. Pet. Tech., January, 1921, p. 26.) It may possibly have been too late to include this in the present volume, but Mr. Evans will doubtless discuss this modification in the next edition of his book, and the possibilities of its use with lubricants suitably diluted.

The other chapters are of much less merit, mainly on account of their extreme brevity or doubtful relevance; they include paragraphs on the oxidation of petroleum as productive of asphalt, on oleography, on oil refining, and on selection of lubricants for specific purposes. We should have much preferred expansion under these headings at the expense of the chapters on the history of petroleum (entirely out of place in a work of this description), on the occurrence of fatty oils (too short to be of any great value), and on oils employed, the last a most unfortunate inclusion in its present form, since it savours strongly of advertisement, which we deplore in any technical or scientific work. While venturing to make the above suggestions, in compliance with the author's request expressed at the close of his preface, we most strongly urge the deletion of pages 112, 113, and 114, together with the fourth paragraph on page 115, in future editions of the book.

H. B. MILNER.

The Technical Examination of Crude Petroleum, Petroleum Products, and Natural Gas. By W. A. HAMOR, M.A., and F. W. PADGETT, M.S. Cloth, octavo, 600 pages, illustrated. Price 36s. net. New York and London: McGraw-Hill Book Company.

The well-known text-book on the American Petroleum Industry by Messrs. Bacon and Hamor, finds a valuable and practical supplement in the present work by Messrs. Hamor and Padgett, in which chapters 4, 11, 12, and 17 of the former volume are here elaborated into eight, with two additional sections and an appendix of 272 pages, the latter itself constituting an oil chemist's *vade mecum* of exceptional practical value.

This book deals principally with the technical examination of crude petroleum, petroleum naphtha products, illuminating and lubricating oils, greases, bituminous road material, natural gas, and the distillation of oil-shale, while in view of the ever-increasing importance of benzol as a motor fuel, a chapter on benzol-recovery plant operation has been contributed by Mr. F. W. Sperrs, Jr., of the Mellon Institute of Industrial Research, University of Pittsburgh. Great care has been taken in describing the various standard methods adopted in

each case, and in many instances alternative methods are discussed, the outcome of recent research, thus enhancing the value of the work and bringing it entirely up to date.

The sections of particular merit are undoubtedly those treating of the examination of bituminous road materials and the examination of natural gas. In the former case the several physical and chemical tests applied to bituminous materials are described in systematic detail, and the methods employed are essentially those which have been thoroughly worked out in the laboratories of the Office of Public Roads, United States Department of Agriculture. The examination of natural gas comprises sampling, determination of density, heating value, analysis, estimation of amount of gasoline content, evaluation of carbon black, and measurement of gas (calibration of meters, etc.). In this country there is comparatively little opportunity for conducting investigations of this character, and consequently our knowledge of the latest methods is usually restricted, except in special circumstances; we therefore not only welcome this comprehensive summary of natural gas examination, but we are strongly tempted to obtain gas samples from Heathfield, Sussex, if only to test the efficiency of the method and apparatus for analysis described and figured on page 257, the outcome of some excellent work by Burrell and others at the United States Bureau of Mines. (See also Bureau of Mines Technical Paper 87).

Possibly a mild criticism of the book may be levelled at the totally inadequate treatment of oil-shale evaluation, which had far better have been omitted as inapposite to the volume than included in its present form. The whole question of retorting oil-shale is so controversial and our knowledge of commercially efficient methods so ramified, that the barest outline of the subject is more misleading than useful, particularly in the absence of any generally recognized standard method of distillation; we welcome in this connection, however, the description of Mr. C. L. Jones' method and apparatus, devised at the Mellon Institute, which certainly seems to obviate some of the more usual difficulties encountered in laboratory shale retorting, such as variations of temperature, uniform heating, and the prevention of condensation of volatile matter within the retort.

We certainly do not ever remember having read an appendix to a technical treatise of such great length and utility as that incorporated in the present volume; printed in smaller type and crowded with tables of constants, viscosity curves, additional methods of examination of oils and bituminous material, diagrams and illustrations of further apparatus, it constitutes the requisite amount of elasticity of treatment of the subject matter commensurate with the scope of the work. As a matter of convenience, we would suggest the inclusion in future editions of a contents page prefatory to this section, in view of its magnitude and importance.

The authors challenge us to critical analysis of their index by the following quotation from Horace Binney, printed at the head of page 573, and to which we venture to draw the attention of many scientific writers of to-day: "The best book in the world would owe the most to a good index, and the worst book, if it had but a single good thought in it, might be kept alive by it." We congratulate the authors not only on the excellence of their index, but also on the production of a work of exceptional merit and utility, a most valuable addition to existing literature on the technical analysis of petroleum and petroleum products.

H. B. MILNER.

A Text-Book of Geology. Part 1. Physical Geology. By LOUIS V. PIRSSON. Second edition, revised. Cloth, octavo, 970 pages, with maps and illustrations. Price 17s. 6d. New York: John Wiley & Sons; London: Chapman & Hall, Ltd.

The appearance of a revised edition of this well known text-book within five years of the first issue speaks well both for the popularity of the work and for the intention of the author to keep his text-book up to date. The author deals with his subject in the usual order, discussing first the action of the various destructive and constructive agents. He is careful to impress on the student that the chemical action of air is dependent on the presence of water, which is important, as dry air has practically no chemical action on the rocks. The chapter on the geological work of organic life gives a treatment of the subject which is much more detailed than in many of the geological textbooks. It would perhaps have been more logical to deal with earth movement before discussing vulcanicity, but this is a point of minor importance.

Section 2 deals with structural geology, including the structure of the earth, composition and tectonics of sedimentary, igneous, and metamorphic rocks, fractures and faults, mountain building, and ore deposits. The plan of dealing with tectonics under the various rock types has much to be said in its favour, but the classification of the igneous rocks includes the term "felsite" which has too many applications to

be satisfactory, and syenites are described at one place as being devoid of quartz and at another as containing quartz in small proportions. The chapters on faults and mountain building are excellent.

The growing importance of geology as an economic science is indicated by the presence of a chapter on ore deposits. One could wish that the author had referred to economic deposits other than those of the metals, and the statement on page 411 that "metallic copper and silver may be also produced by the oxidation and alteration" needs revision.

There is an appendix dealing with the physical and chemical properties of the more important rock-forming minerals, and a selection of some ore-minerals, which does not, however, include any minerals of tin or tungsten.

The book is well illustrated by photographs and diagrams, and it is of interest to note that the photographs are by no means restricted to American examples, as is often the case in American publications. The print is excellent and the index appears to be full and complete. At the end of the book is a geological map of North America of sufficiently large scale to be really useful. The text-book can be thoroughly recommended to the geological student.

E. H. Davison.

☛ Copies of the books, etc., mentioned under the heading "Book Reviews" can be obtained through the Technical Bookshop of *The Mining Magazine*, 724, Salisbury House, London Wall, London, E.C.2.

NEWS LETTERS.

MELBOURNE.

The Coal Output.—The decrease in the coal output of Australia is causing much anxiety. In 1913, 12,500,000 tons were produced, and although figures are not yet available for the year just closed, it is not expected that the total output will reach 9,000,000 tons. In the same period the number of men engaged in the industry has increased by 1,267. In 1913 the production of coal per man was 553 tons, in 1919 it was 540 tons, and for 1920 it is expected to be about 490 tons. Mine-owners generally are alarmed at the continued reduction of output, and there is a feeling that matters are rapidly approaching a crisis. Although at present the strike of the marine stewards and the consequent hold-up of inter-state shipping have slightly eased the position in regard to local supplies, there is still a serious shortage of coal, and at Newcastle the delay to vessels awaiting shipment is as bad as ever.

This great fall in output, owners believe, is due to the deliberate policy of a section of the miners. Within the years covered by the figures quoted, the eight-hour bank-to-bank system came into force, but any reduction in the output through this shortening of hours should, they contend, be more than made up by the increased number of men employed in the industry, and the greater efficiency of the modern mine equipment which has since that time been installed. The proprietors believe that the extremists among the members of the Colliery Employees' Federation are out to make private ownership of coal mines an impossibility, and that one of the methods they have adopted to achieve this end is the go-slow policy, with its consequent reduction of production. At present the miners are working the eight-hour bank-to-bank system, which includes the time taken in descending the pit and arriving at the coal face, the return to the surface, and the dinner hour. This means that actually the miner works much less than eight hours per day. In some pits the working hours are a little more, but generally the owners state that the period of labour averages six hours. The Australian output to-day is about six million tons a year below present market requirements, and about one million tons below what is required for Australasian consumption. The miners, since 1913, in addition to their claims for eight hours bank to bank, have had granted to them increases in wages averaging 8s. 6d. per day. They are, however, dissatisfied with their conditions, and are now claiming, among other concessions, a six-hour day and a five-day week, the abolition of the contract system, and a minimum weekly wage. Of these claims the most important is that for the reduction of hours to six per day. As has already been stated, the coal production of Australia is below requirements and a further reduction equal to 25%, which is believed to be certain to follow the granting of a shorter working day, must inevitably affect the whole of the industrial life of Australia.

Production, as far as efficiency of machinery and general handling methods are concerned, has reached its greatest point, while the employment of additional men has already been under consideration and found impracticable. The demands for a six-hour day and a five-day week are put forward by the miners for health reasons. Coal mining they say is an unhealthy occupation, dangerous and arduous. In reply to this contention owners declare that the occupation is no longer an unhealthy one, and that the average coal miner is just as healthy

a person as any other in the community. The mines are well ventilated, the temperature even, and there is little dust. In New South Wales, they point out, the conditions are altogether different from those existing in other parts of the world. Here the thickness of the coal seam reaches to over thirty feet, and the mines are large and roomy. In England the miner has to work on a seam as thin as eighteen inches, and averaging about five feet thick. Again, in the local mines there is practically no dampness, while the dangers below are no greater than on the surface.

VICTORIAN MINING.—A review of the operations of the Victorian Mines Department during 1920, made by the Minister of Mines, shows that the Ministerial view of the prospects of mining during the current year is quite hopeful. The outlook for gold-mining is considered brighter for the new year. On the Bendigo field the results of recent surveys give further insight into the features of gold deposition, and an extensive memorandum, accompanied by a complete topographical and geological plan of an area of over 30 square miles, is being printed. This memorandum will serve as a guide to future prospecting. At Blakeville a survey of this one-time goldfield has been carried on, and it has reached the limits of the Blackwood field, where detail work will be continued in the new year. To prove the existence of a deep lead in the neighbourhood of Springdallah a drill was engaged for a time, and it located a narrow vein of wash. The Harrietville field is again attracting attention, and several good mines are in operation. At Daylesford the Ajax North mine is opening up large bodies of ore in new ground, and the prospects of adjacent mines are brighter. In the Wood's Point district surveys of several mines show improved prospects. The Rose of Denmark has found a new shoot of gold ore 625 ft. south of the shaft at a depth of 500 ft. below the adit level, with prospects of 650 ft. of backs on this formation. The A1, in addition to operating on ore of average value for the past ten years, is now developing lodes below the worked formations, and these are opening up satisfactorily in untried ground. The Morning Star, after five years' work, has discovered payable values at the 500 ft. and 600 ft. levels. This work was carried out chiefly by the guidance of the Geological Survey officers, and assisted financially by the Mining Development Act. The company is now resuming sinking operations to test the dyke at greater depth. The New Loch Fyne, at Matlock, operated on ore averaging over an ounce to the ton at a depth of 100 ft. below the adit level. This work was also carried out with the collaboration of the Survey and the company. Shortage of labour has handicapped the further development of this promising mine.

Dealing with the prospects of coal, the report says that plans of an area of about 10,000 ft. square at Morwell have been completed. Surveys in the vicinity of Traralgon, in co-operation with boring, have extended the brown coal-bearing areas, proving a maximum thickness in one bed of 650 ft. Two drills are now engaged in this locality. Plans embracing an area of 400 square miles have been completed. At Lal Lal boring is proceeding. On the Tyers river area boring is in progress to delimit the north-eastern extension of the Morwell open-cut area. At Herne's Oak, south of the power-house site, drilling is in progress for brown coal. The brown coal deposits in the vicinity of Corner Inlet are being tested, a drill being worked at present near Gelliondale. Hand-boring is in progress at Wonwron, where a seam 140 ft. in thickness with 8 ft. of overburden was proved. Near Winchelsea, a deposit of brown coal was brought under notice, and further testing of this deposit is now in hand. At Yaloak Vale, south-east of Ballan, a bed of brown coal averaging 4 ft. in thickness was opened, and tests of this deposit are in progress. On the eastern side of the Koo-wee-rup Swamp boring has been commenced, with a view to finding brown coal in this vicinity. In the South Gippsland fields an area of 600 miles was surveyed. This now completes the topography and geology of the country from a line south of Warragul eastwards to Rosedale, and from the Melbourne-Sale railway line to the Melbourne-Port Albert line. Boring has been continued in the vicinity of Korumburra for black coal, and while the results have so far proved only small seams the increasing demand for black coal for locomotive use and gas purposes warrants still further search in this area, where a drill is now at work. Subsidized boring for the Jumbunna Co. has led to the extension of the known area of coal within their lease. A detail survey of the parish of Tanjil East has just been completed, and the result was availed of by the electricity commissioners in connection with their work.

In the Narracan district further outcrops of bauxite have been discovered, and with the advent of cheap power from the Morwell scheme the production of aluminium may be possible in the near future. At Nowa Nowa an examination of the iron deposits was made and data collected, which led to new interest being

directed to the locality. Sands for the manufacture of superior qualities of glass were examined in the Otway Ranges, and their suitability demonstrated by laboratory tests. In the north-east of the State surveys are being continued. Plans of the parishes of Walwa, Thologolong, Burrowye, and Koetong were issued recently. The geology of this area is of interest, as forming a correlation of the Victorian and New South Wales mineral belts. On the plans the outcrop of lodes containing molybdenite, wolfram, scheelite, tin, and fluor-spar are shown. The fluor-spar lodes are now attracting attention, as are also the scheelite and wolfram veins.

VANCOUVER, B.C.

FIRE AT BRITANNIA MILL.—On the night of March 19 the Britannia Mining & Smelting Company's 2,500-ton concentrating plant was completely destroyed by fire. The loss is estimated at one and a half million dollars, only part of which is covered by insurance. The mill, which was the largest and most complete in the Province, consisting of jigs, tables, and flotation cells, took more than a year to build, and was finished only in 1916. The Britannia is a subsidiary of the Howe Sound Mining & Smelting Company, and is the most financially solid copper concern in the Province. The mill was closed on November 30, on account of the low price of copper, but between two and three hundred men have been steadily employed throughout the winter on development work. The fire is supposed to have been due to a short-circuit, as the electric lamps gave a flicker before the fire broke out. The fact of the mill being closed at the time and the fire-fighting appliances being inside, delayed access to this apparatus, and undoubtedly was the cause of the total destruction of the mill. The fire is supposed to have been accelerated, too, by the fact that it broke out near to where the flotation-oil was stored, and it is thought that this oil added considerably to the speed with which the fire spread, as the whole building seemed to be in flames within a few minutes after the outbreak. Fortunately, the men were able to confine the fire to the mill, so no men will be thrown out of work by the conflagration. It had been the intention of the company to re-start the mill this spring. The president of the company, E. B. Schley, is in Europe, and until he has been consulted plans for rebuilding cannot be made. There is no doubt, however, but that the mill will be rebuilt. The Britannia has an actual ore-reserve of more than nine million tons that will average 2% copper and a small gold and silver content. Last year the company turned out 18 million pounds of copper. The concentrate made at Britannia Beach, in Howe Sound, is smelted in Tacoma, in the State of Washington.

PREMIER.—After a short spell of mild weather, which caused a temporary cessation in the transport of ore from the Premier mine to Stewart, cold weather has set in again, and shipping has been resumed. The Prince Albert, which sailed from Stewart on March 20, brought 700 tons of ore, valued at about $300,000, from the Premier to the Tacoma smelter. The contract for the aerial tramway has been let to the Riblet Tramway Company, of Spokane, Washington. The tramway will be between 11 and 12 miles long, and there is a fall of 1,400 ft. between the mine and tide-water. Ore-bunkers, with an automatic unloading device, are to be erected near the wharf at Stewart. The tramway will cost in the neighbourhood of a quarter of a million dollars. It is hoped that the heavy machinery may be hauled to the mine before the present hard crust of ice breaks, as this would considerably hasten the speed of construction.

YUKON LEAD.—The Dominion Government has granted incorporation to the Mayo Valley Railway, Ltd., for the purpose of building a line 50 miles in length along the Mayo and Stewart rivers to open up the new silver-lead mining district in the Yukon Territory. Considerable work has been done during the winter at this camp, and the Yukon Gold Mining Co., the biggest operator, already has more than 2,000 tons of ore at Mayo Landing. This ore is said to average 200 oz. silver per ton and 65% lead. It is expected that another 1,000 tons will be delivered at the Mayo Landing before navigation opens.

OIL INVESTIGATIONS.—There has just been published from the Provincial Department of Lands a pamphlet, entitled "Report of the Oil Surveys of the Peace River District," by John A. Dresser and Edmund M. Spieker. Professors Dresser and Spieker were employed by the Department of Lands to complete the work started by the late J. C. Gwillim in the summer of 1919, and they spent July, August, and part of September in the district last year. Professor Dresser and his assistants made a survey of the ground immediately west of the Peace River Block, which is a Dominion Government forest-reserve, while Professor Spieker surveyed a strip of land some 10 miles wide and 40 miles long trending in a south-east direction immediately south of the Peace River Block. Neither geologist found indications of

oil, but both found geological formations suitable for its retention and similar to that in which oil occurs in other parts of western Canada. Professor Dresser sums up as follows: "The character of the St. John shales strongly suggests that they are oil-bearing, but accumulations of commercial value can only be expected in the porous sandstone beds within the shales or in the upper part of the Bullhead sandstones immediately beneath them. Such accumulations are most likely to occur in the folds of the rocks, principally in anticlinal or upward folds. Along the Peace River one such fold appears near Hudson Hope and another at the "Gates" of the Peace, 7 miles lower down the river. Other folds, probably related to these, were also found on the Red River, near the trail of the South-west Halfway; on Lynx Creek, near to the trail leading to the forks of the Halfway; and on the South-west Halfway, near the trail leading to Hudson Hope. These are the most promising localities for the discovery of oil yet found in the area. In view of the unlikelihood of finding better structures and of the limited amount of other information likely to be obtained in the area by further field examination alone, it seems advisable that the next step in search of oil should be made by exploratory drilling."

Professor Spieker, with regard to the land he surveyed, sums up: "A conclusion regarding the advisability of exploration with the drill must naturally be based on the balancing against one another of the favourable and unfavourable facts (not opinions) which have been gathered. Without attempting at the differentiation of geologic and economic data, these facts may be summed up as follows: Unfavourable factors: (1) Absence of evidence through seepage or other appearance of petroleum in the rocks; (2) the great cost of transporting drilling equipment to any of the advisable locations; (3) in corollary of the preceding, the expense attached to the disposal of such petroleum as might be found. Favourable factors: (1) The presence of a number of locations in which oil could occur; (2) the presence of anticlines which dispose the possibility of oil-bearing strata favourably to the retention of petroleum; (3) the comparatively reasonable depth within which the beds to be tested may be reached. As a whole the region may be classed on the basis of geologic evidence as a fair prospect."

Some two years ago, the D'Arcy Development Company, a subsidiary of the Anglo-Persian Oil Company, sought from the Provincial Government the sole right to explore over an area 70 miles square in this district, agreeing within 5 years to select an area 10 miles square, and surrendering the balance to the Province. The company further agreed that, in the event of the discovery of petroleum in commercial quantities, it would construct pipe-lines or provide other means to make it available and would pay a royalty of 12 cents per barrel at the casing head. The majority of the mining engineers in the Province are agreed that the Government made a mistake in not accepting this offer. The Government, however, claims that it is preserving the oil lands of the Province for the benefit of the Empire. Exactly what value to the Empire the oil areas of the Peace River district could ever be in their present undeveloped state none but the Government can fathom.

TORONTO.

April 12.

PORCUPINE.—The power situation, which has latterly been improving, is now completely satisfactory, and the mining companies are receiving their full requirements. Production at the Hollinger Consolidated, Dome Mines, and McIntyre is now being speeded up, with the output closely approaching the normal volume. Labour is plentiful and efficient. Many miners, released from the silver and nickel camps, are flocking into Porcupine. The Hollinger and the McIntyre are making every effort to find accommodation for the new-comers, and are erecting a number of additional houses for their employees. The drawbacks of power shortage and labour scarcity having ceased to hamper production, a period of great activity is anticipated. The Hollinger has ordered 30 additional machines for underground work so as to take on additional forces. At the Dome Mines two large ore-bodies have been encountered at the 1,050 ft. level, the ore showing considerably higher gold content than the average. The ore sent to the mill is now 50% higher in gold content than the pre-war grade. The North Crown has struck rich ore in a drift at the 500 ft. level, the gold content running as high as $20 per ton across the face of the drift. The Porcupine Keora has arranged to sell two of its claims to a new company to be organized with a capitalization of $3,000,000, two-thirds of the shares to be retained by the Keora. The company will still have three claims with an area of 120 acres. The Allied Porcupine Gold Mines has been organized with $5,000,000 capital to take over the La Palm and Three Nations properties and possibly other holdings. Peter Kirkgaarde, of Toronto, has been placed in charge of opera-

tions. Operations have been resumed at the Premier Paymaster, south-west of the Dome. Diamond-drilling is being undertaken to determine the extension eastward of a large ore-body opened up on the 200 ft. level. The Porcupine Miracle, which is preparing for active development, has increased its capitalization from $1,000,000 to $2,000,000.

KIRKLAND LAKE.—The season has opened actively in this camp with quite a number of new enterprises entering the field, especially in Lebel Township. The Lake Shore during February produced $24,068 from the treatment of 1,458 tons of ore, being an average extraction of $16·44 per ton, the mill running 83% of possible time. The Kirkland Lake has encountered a new ore-shoot on the 700 ft. level, which has been opened up for 100 ft. The drift on the 600 ft. level has entered the same body. Development work is being carried on at five levels. At the King Kirkland the shaft is down 100 ft. on a vein the full width of the shaft with highly satisfactory results. Assays of channel-samples taken at intervals down give varying results, with an average of $11·60 per ton. A new company, the Queen Lebel, has been formed to take over three mining claims lying south of the east end of Gull Lake, on which a number of promising veins have been found. The shaft of the Lebel-Oro has reached a depth of 50 ft. on a vein carrying commercial gold content. The Kirk Gold Mines is making arrangements to operate three claims adjoining the King Kirkland on the west in the line of the strike of the ore-bodies found in the producing area. The Teck Hughes mill is working to capacity, treating about 125 tons of ore per day. The company is planning to increase its milling equipment. The Bidgood will undertake a large amount of underground work, including the deepening of the main shaft from 300 to 500 ft. D. H. Angus, of Cobalt, has been placed in charge.

COBALT.—The silver-mining industry continues much depressed. It is hoped, however, that the new wage schedule, under which wages are cut 75c. per day, which went into effect on April 1, may result in some revival of activity. It is estimated that the lower wage means a reduction of from 3 to 5c. per oz. in mining costs, which may give some mines now idle an opportunity for profitable operation. The Nipissing during February produced silver to the value of $111,931 and cobalt valued at $12,460, and shipped bullion from Nipissing and custom ores of an estimated net value of $235,374. The annual report of the La Rose for 1920 showed that production amounted to 410,445 oz., valued at $313,995, compared with 289,317 oz. of the value of $356,124 in 1919. The profit on production was $13,279. While there are several sections of the parent property which will warrant further investigation, G. C. Bateman, the general manager, does not consider that the work would be justified at present owing to the low price of silver. A quantity of exceptionally rich ore is being taken from the University property of the La Rose. The Mining Corporation of Canada is making extensive alterations in its mill, designed to increase the capacity from 200 to 300 tons daily. It will require at least a month longer to complete this work, and in the meantime productive activity will remain suspended. The Kerr Lake has exercised its option on the Hargraves property adjoining, which it is operating from its own underground workings. The Northern Customs Concentrators, Ltd., has gone into liquidation.

SUDBURY.—The first mortgage bond-holders and debenture stock-holders of the British American Nickel Corporation have approved a scheme for the financial reorganization of the company by the issue of $24,500,000 in income bonds of three classes, a portion of which will be hypothecated for debts, $2,000,000 retained in the treasury, and the remainder exchanged for first mortgage bonds and debenture stock. Minority interests are taking legal proceedings to prevent the arrangement being carried out.

FLIN-FLON.—The New York syndicate, headed by Col. W. B. Thompson, which held an option on the Flin-Flon copper deposit in Northern Manitoba which expired March 31, allowed it to lapse after having expended over $200,000 in development work. The low price of copper and the tightness of the money market are the reasons assigned for failing to take over the property. The ore-body is estimated at about 24,000,000 tons, but its operation, including the construction of a railway, the establishment of a new mining town, and the development of power, might involve a total expenditure of $20,000,000. Negotiations are now under way for the purchase of the mine by a new syndicate, headed by the Mining Corporation of Canada, which held a fourth interest in the New York syndicate.

MACKENZIE RIVER OILFIELD.—Interest in the oil discoveries near the Arctic Circle continues active, though prospectors have been somewhat discouraged by the provision in the new regulations under which when a discovery is made three-fourths of the area included in the prospector's licence reverts to the Crown. A number of oil issues, some of them of doubtful character, are being placed on the market.

Representatives of several British companies are in Northern Alberta looking after their interests, and the coming season will witness much activity in exploration. A bill in the interests of the Imperial Oil Co., authorizing the construction of a pipe-line from the Mackenzie River oilfield, is before the Alberta Legislature. It is meeting with strong opposition from other interests, who contend that any pipe-line authorized to be built should be constituted a common carrier, available for the product of all operators, and not a monopoly.

PERSONAL.

CLYDE ALLEN is expected from Nigeria.

DR. CHARLES ANDERSON has been appointed Director of the Australian Museum, Sydney.

PROFESSOR C. O. BANNISTER, of Liverpool University, is the recipient of an Andrew Carnegie Research Award of £100.

F. O'D. BOURKE is here from Nigeria.

W. E. CAMERON has been appointed Mining Geologist to the Federated Malay States Government.

A. D. COMBE has been appointed Assistant Government Geologist in Uganda.

W. H. CORBOULD is expected from Mount Elliott, Queensland.

PAUL S. COULDREY has left British Columbia to take an appointment in Spain.

CLEMENT DIXON is visiting Central Europe.

W. R. FELDTMANN is back from West Africa.

B. L. GARD'NER has left for Selangor to take up an appointment as Inspector of Mines.

PHILIP GRIMLEY is home from Nigeria.

DR. J. A. L. HENDERSON is back from Canada.

HARLEY E. HOOPER has returned to Adelaide from Burma, where he was for some years on the staff of the Kanbauk Burma Wolfram Mines company.

J. M. ILES is here from Nigeria.

A. F. KEENE is here from New York.

ELDRED A. KNAPP has gone to Venezuela.

H. W. LAWS has returned from Nigeria.

ARTHUR E. LEWIS has gone to Ipoh, Perak.

EDWARD P. MATHERS has gone to South Africa.

E. P. MATHEWSON will be leaving shortly on his return to New York.

L. H. McLAGGAN has returned from West Africa.

A. H. P. MOLINE has been here from Australia, and is returning by way of South Africa.

C. ALGERNON MOREING has had conferred on him by the President of the French Republic the Order of the Legion of Honour.

R. J. MORGAN has returned to Sydney from Siberia.

CLIFFORD W. NASH has opened an office in Melbourne, where he will practice as a consulting metallurgist.

J. A. T. ROBERTSON has left Missouri for Yunnan.

W. R. RUMBOLD is back from Portugal.

WILLIAM SELKIRK has returned from India.

R. C. SHARP has returned from South America.

RALPH S. G. STOKES, assistant general manager in the mining department of the De Beers Consolidated Mines, is visiting England on long leave.

DR. O. J. STANNARD is back from the United States.

H. PLAYFORD TUCK has joined the staff of the Electrolytic Zinc Co. of Australasia in Tasmania.

PAUL M. TYLER is here from the United States.

F. G. WILSON has been appointed manager for the Austral Siamese Tin Company.

YEATMAN & BERRY have moved their office from 111, Broadway, to Room 1,604, 165, Broadway, New York.

T. E. GATEHOUSE, for forty years editor of the *Electrical Review*, died on March 31. He was an editor of discrimination and high honour, and he was also endeared among the electrical profession by being a musician and violinist of no mean order.

BERTRAM BLOUNT died last month in his 54th year, after a long illness which supervened on strenuous war work. He was known in many departments of chemical engineering, and wrote books on cement, electrochemistry, and chemistry for engineers. His paper and investigations on the accuracy of chemical balances aroused much attention among metallurgists; this matter was referred to in our pages early in 1918.

A. J. C. MOLYNEUX, a member of the Rhodesian Geological Survey, died last December. He originally went to Rhodesia in 1893 with Major Alan Wilson's force which occupied Matabeleland. After the country was settled, he made many geological expeditions. His most important work was the discovery of several of the coalfields in Rhodesia, and his correlation of these deposits with the Karroo Coal Measures. He was the founder and first secretary of the Rhodesia Scientific Association, and one of the first trustees of the Rhodesia Museum. He joined the Geological Survey in 1917.

RICHARD A. VARDEN died last month. He was a graduate of Clausthal, and his first appointment was at the Wohlfart mines in Germany. Subsequently he went to the United States and Mexico. In 1895 he went to West Australia as manager of Hannan's Brownhill mine. In 1897 he joined Bainbridge, Seymour & Co. as Australian partner, and later became a London partner of the firm. In 1910 he became Australian partner of Hooper, Speak & Co., and continued in that capacity until 1918, when he retired from active practice. While in Australia for Hooper, Speak & Co., he was chiefly concerned in the management of Great Boulder Perseverance and Ida H. He was a man of singular charm and high character. That he lived so much abroad was always regretted by his confreres in England.

TRADE PARAGRAPHS

THE HENRY WELLS OIL CO., of 11, Haymarket, London, S.W.1, send us a pamphlet describing the "Germ Process" lubricating oils.

THE SWAINSON PUMP CO., LTD., of Newcastle-on-Tyne, have put on the market a new hand-pump suitable for use in mines.

BULLIVANT & CO., LTD., of 72, Mark Lane, London, E.C.3, and Millwall, send us a copy of their revised catalogue of steel wire ropes and accessories. The catalogue contains illustrated descriptions of a great variety of applications of the firm's ropes.

THE EDGAR ALLEN NEWS for May, published by EDGAR ALLEN & CO., LTD., Imperial Steel Works, Sheffield, contains articles on the design of furnaces for heat treatment by S. N. Brayshaw, and on the importance of shape in rock-drill bits.

THE WESTINGHOUSE ELECTRIC INTERNATIONAL CO., of 165, Broadway, New York, publish a monthly magazine called the "Westinghouse International." The April issue deals with several of the firm's specialties and also with the outlook throughout the world for electrical business.

METROPOLITAN-VICKERS ELECTRICAL CO., LTD.,

of Manchester, and 4, Central Buildings, Westminster, send us leaflets describing high-tension contactor panels and Star-Delta contactor starters; also a pamphlet relating to the installation and operation of the firm's power transformers. They also send us their pamphlets relating to their turbo-alternators and electric arc welding.

THE ENGLISH ELECTRIC CO., LTD., of Queen's House, Kingsway, London, W.C.2, send us a new publication relating to steam turbines. This firm is a recent consolidation of Dick, Kerr & Co., of Preston, the Siemens Dynamo, of Stafford, Willans & Robinson, of Rugby, the Phœnix works, Bradford, and the Ordnance works, Coventry. The steam turbines of this firm are specially adapted to the driving of great alternating-current dynamos.

SIR W. G. ARMSTRONG, WHITWORTH & CO., LTD. (civil engineering and contracting department, 8 & 10, Great George Street, Westminster), have obtained the contract from the Crown Agents for the Colonies for the Ebute Metta workshops, which are to be erected near Lagos for the Nigerian Government Railways. The contract calls for the supply, erection, and equipment of new locomotive shops, carriage and wagon shops, an electric power station, saw-mills, etc.

SUBMERSIBLE MOTORS, LTD., of Southall, near London, have issued particulars of their electrically-driven pumps for mines. The vertical type of submersible motor-pump is adapted for use in sinking operations. The construction is such that the apparatus takes up very little room in the shaft; there are no awkward or projecting corners and angles; the pump can be very quickly slung in chains or on ropes; and it is immaterial as to what angle the pump is suspended. The advantage of being able to lower the pump and motor into water until the apparatus is either wholly or partly submerged without it losing in reliability or efficiency is incalculable. Sinkers frequently use these pumps as a standing, when drilling their sumping and side holes. The horizontal type is adaptable for practically any emergency in mines, and can be installed at a shaft bottom or any part of mine workings with complete confidence and safety. In cases of accumulations of water, in dip or deep workings, a submersible motor pump is of peculiar advantage. In these cases the apparatus can be securely fastened to a skid or low trolley and lowered completely into the water. No undulations of the floor, in whatever direction, have any adverse effect on the pumps. The reliability of these pumps can be exemplified by the installation at Pengam Colliery in Monmouthshire. Here a 6 in. single-stage pump was started on May 6, 1920, and has been continuously at work for over nine months, for the greater part of the time running 24 hours per day for weeks together. During the whole period the motor-pump was working entirely submerged, and has only been raised twice for examination, when everything was found to be in excellent condition.

THE BUILDING TRADES EXHIBITION, OLYMPIA.

The Building Trades Exhibition at Olympia was open for two weeks, from April 12 to 26, and attracted a large number of visitors. To mining engineers concerned in the housing of their employees it offered many points of interest, particularly in regard to the materials of which houses may be built nowadays. There were many exhibits by firms known among mining men, of which brief notes are given in the following paragraphs.

G. A. HARVEY & CO. (LONDON), LTD., of 5, Laurence Pountney Hill, London, E.C.4, and Woolwich Road, E.14, showed galvanized iron tanks and also screens of perforated metal and woven wire.

THE MOLER FIRE-PROOF BRICK & PARTITION CO., LTD., one of the Vickers group of companies housed at Vickers House, Broadway, Westminster, with works at Colchester, had an exhibit of fire-proof and sound-proof bricks, and bricks suitable as insulating boiler coverings. The material used is diatomaceous earth obtained from Denmark. The deposit was described by E. A. Manners in the MAGAZINE for March, 1916.

FERODO, LTD., of Chapel-en-le-Frith, showed their fibre stair treads. Ferodo is known among engineers as a surface material for brakes and clutches.

THE STURTEVANT ENGINEERING CO., LTD., of 147, Queen Victoria Street, London, E.C.4, confined their exhibit to ventilating fans and vacuum cleaners.

THE WILFLEY COMPANY, LTD., of Salisbury House, London, E.C.2, showed their Marbolith jointless flooring.

JOHN & EDWIN WRIGHT, LTD., of the Universe Rope Works, Birmingham, and Salisbury House, London, E.C.2, had an excellent display of their hemp and steel wire ropes.

MILLARS TIMBER & TRADING CO., LTD., of Pinners Hall, London, E.C.2, had an exhibit of rock crushers and air-compressors, and illustrations and models of steam-shovels, cranes, and other machinery.

S. THORNLEY MOTT & VINES, LTD., of 11, Old Queen Street, Westminster, showed "ironite" cement and flooring, hollow concrete blocks for building purposes, Watson bottom-dumping wagons, and concrete mixers. They also showed photographs of the Marion steam-shovel, for which they are agents in this country.

We also observed applications of the DORR plant to sewage treatment and NISSEN huts; these were shown by users and not by the manufacturing firms.

Ready access to the galleries was provided by a special exhibit of lifts made by WAYGOOD-OTIS, LTD., of 54 and 55, Fetter Lane, London, E.C.4.

METAL MARKETS

COPPER.—Remarkable steadiness characterized the London standard copper market during April, and price fluctuations have been very small, despite the coal stoppage and the threat, happily unfulfilled, of a general strike. The fact that demand from consumers is still poor and likely to diminish further under present industrial conditions seems to have had little influence on values, and there is quite an optimistic undertone in the market. In the United States, the price has kept steady around 12¾ cents per lb., and business there is also quiet. During the first quarter of the year, stocks in that country increased, but in view of the recent closing of a dozen or so important mines, production will show a falling off in the near future, and a decrease in the huge American stocks is to be expected. It is understood, by the way, that it will be possible to restart the mines there at very short notice when conditions are favourable to such a policy. The Kennecott Copper Corporation has cut down production, and may later close down completely. The Braden concern has reduced output to some 1,000 tons. Neither the Chile nor Braden companies is expected to shut down, however. The Quincy Mining Co. at Calumet has reduced wages by 10%. Chilean mines, it is understood, are to restrict production, but the Union Minière du Haut Katanga is undertaking fresh development schemes and has no apparent intention of adopting a similar policy.

Average price of cash standard copper: April 1921, £69. 8s. 11d.; March 1921, £67. 13s. 3d.; April 1920, £103. 2s. 11d.; March 1920, £109. 11s. 10d.

TIN.—The standard tin market in London was domi-

nated at the beginning of the month by the coal crisis, and quotations were accordingly depressed. Later, values fluctuated upon every fresh development in the industrial situation, optimism finally gaining the upper hand, with the consequence that prices at the end of the month showed a moderate rise. There had been a general feeling that the bottom had been reached, and the upward reaction was therefore not altogether unexpected. Consuming demand, however, still continues unsatisfactory, and purchases by the Continent have rather tended to fall off of late. Stocks, on the other hand, are well held both here and in the East. Of course, the Federated Malay States Government holds a considerable quantity of metal, acquired at comparatively high prices, but the intention is to wait for a more remunerative level of quotations before liquidating. It had been expected that the Straits mines and smelters would commence curtailing output, but up to the present no definite news is to hand as to what has been done in this direction, although the Nigerian and Bolivian mines have found themselves forced to adopt such a policy. Apropos the general impression that profitable tin production in the Straits is difficult at current market values, it is interesting to observe that the Gopeng company's cost of producing black tin last year was £59. 2s. 3d. (average profit £122. 14s. 4d.), the Rambutan's cost £73. 7s. 3d. (average profit £116. 17s. 6d.), and Tekka-Taiping's cost £69. 3s. 4d. (average profit £108. 2s. 8d.). The Nigerian companies appear to have been harder hit by the fall in tin, and have successfully applied for concessions from the Government in regard to rents and royalties in order to give them some relief. The Straits have been shipping only moderately of late, the figure for April being 1,800 tons, of which 715 tons came to the United Kingdom, 925 tons were taken by the United States, and 100 were despatched to the Continent.

Average price of cash standard tin: April 1921, £164 0s. 11d.; March 1921, £156. 4s. 7d.; April 1920, £345. 13s. 1d.; March 1920, £369. 14s. 5d.

Lead.—The London lead market has kept fairly steady during the past month, the tendency being slightly upwards. Undoubtedly, the feature has been the purchases of Spanish lead direct by America, which has had the effect of somewhat reducing the arrivals in this country. The American buying has been influenced by the apprehension of increased import tariffs in the near future. Practically the only supplier of lead to the London market has been Spain. America is above our parity, Burma sells to the East, the situation in Australia does not permit of supplies from there, while Belgium and Germany send nothing. It was believed that the stocks in Spain were considerable, but owing to the lack of information on the position there it is not known whether further heavy shipments are likely. It is possible, of course, that the United States may later re-export some of the metal recently purchased. News from the producing countries tells invariably of curtailed output. At Fremantle, the smelter of the Fremantle Trading Co. has been shut down owing to the ceasing of supplies from the neighbouring mines. The Chihuahua and Monterey smelters in Mexico have closed indefinitely, while Spanish advices state that the Penarroya Co. has stopped work at the Santa Isabella mines. As regards the United States production, this appears to be generally curtailed except in some cases where the ore is mined for its silver. Stocks in the United States are reported to be large. The March production of lead of the Rhodesia Broken Hill was 1,630 tons.

Average price of soft pig lead: April 1921, £20. 16s. 10d.; March 1921, £19. 2s. 9d.; April 1920, £40. 4s.; March 1920, £47. 1s. 9d.

Spelter.—The London spelter market during April had a firm tendency, prices rising very gradually but steadily. The chief reason for this was no doubt the absence of offers of German metal, owing to the deadening influence of the Reparations Act, and the better sentiment thereby engendered. As long as the Act remains in force, it is difficult to see how Germany, which is believed to be the only producer to whom the present London price is profitable, can continue to export; while the other producers are naturally averse from doing so because prices are too low. Both Belgium and Norway appear to be looking for higher levels before entering the market on a large scale, and America also is not likely to ship anything to this side. Under these circumstances, despite the fact that consuming demand is generally poor owing to the unsatisfactory condition of the galvanizing industry, the tendency certainly appears to be toward higher prices. The Belgian produc-

tion during March showed a reduction on the month of 1,890 tons, being only 4,640 tons. The German output is estimated at around 4,000 tons monthly, but present conditions may force curtailment there also. Belgium is apparently finding a ready market in France and elsewhere for her zinc sheets, so it is more than probable that her stocks will find an outlet in that direction rather than be unloaded on the London market. As regards the American position, the present output there has been estimated at about one-third of what it was a year ago, while stocks are believed to be double. The American quotation has been firmer during the month.

Average price of spelter: April 1921, £26. 1s. 5d.; March 1921, £25. 10s. 5d.; April 1920, £48. 9s. 4d.; March 1920, £54. 16s. 7d.

ZINC DUST.—Business has been quiet, and prices are practically unaltered on the month, as follow: High-grade Australian about £55, high-grade American £55 to £62. 10s., and best English about £60 per ton. Continental material appears to be offering at lower figures.

ANTIMONY.—English regulus has kept steady at £37 to £40 for ordinary brands and at £38. 5s. to £42 for special brands. Foreign regulus on spot is quoted around £25 to £28 per ton in warehouse.

ARSENIC.—The market is stagnant, and Cornish white is nominally quoted at £46 to £48 per ton delivered.

BISMUTH.—The leading interests quote 7s. 6d. per lb.

CADMIUM.—There is only a small demand, but the price is steady at 6s. to 6s. 3d. per lb.

ALUMINIUM.—Producers are nominally quoting £150 per ton for both home and export, but this price would possibly be shaded, especially as there have recently been offers of cheap Continental metal.

NICKEL.—The chief interests made two reductions of £5 in the price during April, and the present quotation is £190 per ton for both home and export.

COBALT METAL.—Demand is quiet, the price being 18s. to 20s. per lb.

COBALT OXIDE.—Black oxide continues at 16s. and grey at 17s. 6d.

PLATINUM AND PALLADIUM.—There is little change to report. The leading sellers of manufactured metal (sheets and wire) have increased their price to £20 per oz. Raw platinum, however, is still reported to be changing hands around £17 per oz. and raw palladium at about £15.

QUICKSILVER. — The market has been easy and quiet. The present quotation is £11. 5s. to £11. 10s. per bottle.

SELENIUM.—The market is quiet, the quotation being 10s. 6d. to 13s. per lb.

TELLURIUM.—Sellers continue to quote 90s. to 95s. per lb.

SULPHATE OF COPPER.—The tendency is still downward, and the present quotation is about £28 to £30.

MANGANESE ORE. — The market is rather quiet, with Indian grades steady at 1s. 4d. to 1s. 5d. per unit c.i.f. U.K.

TUNGSTEN ORES. — This market continues a very difficult one. The current price is about 12s. 6d. per unit, c.i.f., for 65% WO_3, but buyers are waiting for lower figures, while sellers are inclined to hold out for higher prices. Business is consequently restricted.

MOLYBDENITE.—Business is dull, with 85% nominally quoted at 52s. 6d. to 60s. per unit c.i.f. U.K.

CHROME ORES. — The price of Indian and African grades is steady at £5. 10s. to £6 per ton c.i.f. U.K.

SILVER.—The quotation for spot bars at the beginning of April was $32\frac{1}{2}$d., the price rising till $36\frac{1}{2}$d. was attained on the 12th. Subsequently the price fell to $33\frac{3}{4}$d. on the 15th, recovered to $35\frac{5}{8}$d. on the 18th, and later kept fairly steady, closing the month at $34\frac{5}{8}$d.

GRAPHITE.—Madagascar, 80 to 90%, continues to be quoted at £20 to £25 per ton.

IRON AND STEEL.—A further cut in the price of Cleveland pig iron was made at the beginning of April, but any hopes that were anticipated of a revival in trade were dashed to the ground by the coal strike, and the close of the month found production of iron and steel in this country virtually at a standstill. The price of No. 3 Cleveland pig iron is £6 per ton for both home and export, but Belgian foundry iron can be obtained at £5. 5s. c.i.f. It is the same story in the finished iron and steel trades. Most works are closed, and few makers are showing inclination to book for forward delivery, as the whole question depends upon the new basis price of fuel. In the meantime what little business is about is being secured by Continental makers.

THE MINING DIGEST

A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also notices of new books and pamphlets, lists of patents on mining and metallurgical subjects, and abstracts of the yearly reports of mining companies.

ANACONDA ELECTROLYTIC ZINC.

A paper by Frederick Laist and others was presented at the February meeting of the American Institute of Mining and Metallurgical Engineers describing the electrolytic zinc plant of the Anaconda Copper Mining Company, Montana. The zinc ores at this company's group of mines are complex sulphides, and the concentrates average only 35% zinc and are high in iron and lead. After trying the Horwood preferential flotation process for the improvement of these concentrates with discouraging results it was decided to try roasting, leaching with sulphuric acid, and electrolysis of sulphate solutions. The paper is of considerable length and contains many graphs, plans, and photos; we are able only to give an outline of the main points of the process.

Experiments.—The authors, in the first section of the paper, give an account of the facts as ascertained in laboratory examination of the proposed method. They soon found, as had other investigators, that the only way to obtain a good zinc deposit is to have the electrolyte free from all metals more electro-negative than zinc, such as copper, cadmium, lead, arsenic, antimony, etc. Arsenic and antimony are particularly injurious, causing very poor current efficiency and small yield per horse-power when present even in amounts so small as almost to defy detection, 1 mg. or less per litre. A pure zinc is soluble only with difficulty in sulphuric acid; an impure zinc dissolves very readily. Electrolytic zinc deposited from pure solutions is, of course, extremely pure and dissolves only about one-fiftieth as rapidly as ordinary zinc. The dissolving of pure zinc in dilute sulphuric acid can be greatly accelerated by the addition of a few drops of a solution containing copper or arsenic. The presence of these metals in the solution going to the electrolytic cells would have the same effect on the zinc deposit at the cathodes, so that re-solution would set in and might proceed at a rate that would entirely offset the depositing power of the current. In such a case no zinc would result from the passage of the current, and nothing but hydrogen would be made at the cathode and oxygen at the anode. Smaller amounts of impurities would result in the zinc being redissolved, but more slowly than it is deposited, producing cathodes full of holes of various sizes, while the yield per horse-power-day would be proportionally decreased. H. W. Gepp, in experimenting at Bully Hill, California, found that one of the most injurious impurities present in those ores was cobalt. According to him fifteen parts of cobalt per million parts of solution is fatal to electrolysis. The cell work is seriously impaired with only ten parts per million. The cobalt may be precipitated with manganese by the addition of permanganate or it may be thrown down in the presence of manganese by the addition of beta-naphthol and sodium nitrite, also by zinc dust from the neutral solution in the presence of ferric iron, copper, and arsenic. It was not found difficult to maintain an extremely high degree of purity in the zinc solution going to the cells if the iron in the solution was thoroughly oxidized, before being precipitated, by means of limestone or excess calcine, and if sufficient zinc dust was added to satisfy fully the copper, cadmium, and whatever small amount of lead might be present. If the ore contains very little iron, in proportion to its arsenic content, it might be necessary to add iron in the form of ferric salt in order to ensure the complete precipitation of all arsenic as ferric arsenate. It was found that the best way to make sure of the oxidation of the iron was to maintain a small amount of manganese in solution. Manganese becomes oxidized in passing through the cells, forming permanganic acid, manganic sulphate, and manganese dioxide. The ores contain sufficient manganese for this purpose, so that it is seldom necessary to provide outside manganese. It is possible to ensure oxidation of the iron by other means, notably continued air agitation in the presence of milk of lime. An aluminium plate made the most suitable cathode and a lead plate the most suitable anode. The latter quickly becomes coated with a brown layer of manganese dioxide and lead peroxide, and if the zinc solution is entirely free from chlorides the lead is not attacked. Some of the lead anodes have been used for three years and seem to be just as good as when put in. In the beginning it was the intention to use aluminium plates only for building up starting sheets of suitable weight. This, however, proved unsatisfactory, as the starting sheets tended to warp and cause short circuits. Aluminium cathodes are therefore used in all of the cells, and the zinc is allowed to deposit until a sheet of sufficient weight is built up to go directly to the casting furnace. Generally 48-hr. sheets, which weigh about 20 lb., are made, so that about 40 lb. of zinc is stripped each time the cathode is withdrawn. In order to avoid re-solution, good contact must be maintained between the zinc and the aluminium plate. The plate, therefore, must be roughened sufficiently to ensure adherence as the zinc sheet becomes heavier. This limits the weight of zinc sheets it is possible to build up, and this, together with the tendency toward sprouting, limits practice to 48-hr. deposits. Seventy-two hour sheets have been successfully made, but on the average the 48-hr. plates give the best results. The better current efficiency with the younger deposits more than offsets the labour required for more frequent stripping. The experimental work was done with current densities varying from 10 to 100 amperes per square foot. In practice, the most satisfactory density is from 22 to 25 amperes. It is not necessary to circulate rapidly as, with the current density used, the evolution of gas at the anode is sufficient to provide the necessary agitation.

Roasting.—The authors proceed to detail the steps whereby the process was gradually developed, and then describe the process as established at Great Falls. The plant as finally completed has an output of 150 tons of electrolytic zinc per day. Roasting of the concentrates is done partly at Anaconda, where McDougal furnaces are used, and partly in Wedge furnaces at Great Falls. The following is an average analysis of the concentrate and of the resulting roasted material:

	[illegible]	Roasted Material
[illegible]	[illegible]	[illegible]
Cu	1·8	1·0
Pb	9·5	10·3
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]

It was recognized at the beginning that the concentrates must be finely ground to get the maximum solubility; screen analyses of the crushed concentrates show that 67% goes through minus 200 mesh. A low initial temperature of the roast gives better solubilities on concentrates containing appreciable amounts of lead and iron sulphides. Lead, if 5% or more is present, tends to cause the roasting concentrate to sinter and ball up at the higher temperatures; as these agglomerated masses will be insufficiently roasted, poor solubility results, and a larger amount of classifier sand is produced in the leaching plant. The aim is to prevent simultaneous oxidation of the iron and zinc, as far as possible, by keeping the temperature of the two top roasting hearths below the active break-up temperature of zinc sulphide and yet high enough to permit FeS_2 and FeS to oxidize in the time allowed. Unfortunately, zinc sulphide begins to oxidize at the low temperature of the upper hearths but to a less degree than the iron sulphide, and therefore a small amount of ferrate will be formed. If the dross containing a large amount of metallics is fed in with the concentrates, even at the low temperature of the top floors, the formation of ferrates is greatly increased. If the dross is charged to the lower floors, where there is little or no iron sulphide, there is very little formation of ferrates.

The amount of sulphate formed is dependent on a low initial temperature, so that apparently the amount of sulphate formed is largely influenced by the amount of Fe_2O_3 present and the reactions that take place in sulphate-roasting are those of the contact acid process, where freshly prepared ferric oxide is used as a catalyser. The iron sulphide is oxidized to ferric oxide in the top hearths and acts as a catalyser changing the sulphur dioxide from the roasting zinc sulphide to sulphur trioxide which, in turn, combines with the freshly forming zinc oxide to form zinc sulphate. In proof of this, if the temperature at first is high, practically all of the iron will be combined with the zinc to form ferrates, in which case very little sulphate will be formed, although temperatures and sulphur elimination are the same in the lower part of the furnace as when sulphating. The amount of sulphate remaining in the finished calcine is dependent on the end temperature. To decrease the percentage of sulphate and sulphur, it is only necessary to raise the end temperature and break up or prevent the formation of sulphates. While the solubility falls when the sulphates are broken up, it will be better than when ferrates are formed on the top hearths instead of Fe_2O_3.

Leaching.—The leaching is continuous and is carried out in two steps: (1) A neutral leach where all the calcine and approximately one-half of the total acid is added; (2) an acid leach where no calcine and the remainder of the acid is added. The solution for the first, or neutral, leach is made up with one-half of the cell acid (11½% sulphuric acid and 2½% zinc) and the partly spent leach liquor (0·6% sulphuric acid and 10% zinc from the acid leach). This mixture is run into the first of a series of seven continuous-leaching Pachuca tanks. Sufficient iron must be present and oxidized to account for all the arsenic and antimony, otherwise they will not be removed and poor tank-room efficiency will result. Calcine is run into the three succeeding Pachuca tanks in such a manner that there is an average drop of 2½% acid in each tank. Nothing is added to the fifth tank, as it is used as an indicator, or control, tank in which the acid should be nearly, or completely, spent. One-sixth of the total amount of calcine is added to the sixth Pachuca tank, together with a small amount of pulverized limestone. The excess base contained in the calcine and lime rock completely precipitates the ferric iron, granulates the gelatinous silica, and partly precipitates the copper. These chemical precipitates, together with the insoluble residue, carry down the freshly formed insoluble compounds of arsenic and antimony, and completely free the solution from them. For instance, the arsenic may be as high as 2 grams per litre in the liquor of the third Pachuca tank and less than 1 mg. in the seventh Pachuca, which is also a control tank, but its function is mostly physical. After the base is added it takes several minutes for the leach to coagulate. If this step is carried out too rapidly, poor settlement results, and in a short time the rest of the plant will be blocked with mud. When this step is properly carried out, each granular particle of solid appears to be enclosed in a flake of freshly precipitated iron, lime, or gelatinous silica; that is, each solid particle becomes a nucleus about which the chemical precipitate collects and provides the necessary weight to carry down these flaky particles. The capacity of the settling equipment is dependent on the proper handling of the seventh Pachuca. It is easy to control, but requires close attention. The discharge of the last Pachuca goes to the neutral classifiers. These take out the sands, which are re-ground and returned to the system for further treatment. The overflow from the classifier flows to Dorr settlers, which discharge a clear overflow for the purification tanks, and a spigot product, containing 50% solids, which forms the feed to the acid leach.

In this neutral leach, all the calcine enters the process and approximately three-fourths of the soluble zinc is taken into solution; the iron is oxidized and precipitated; gelatinous silica is coagulated by excess base and rendered granular; the arsenic and antimony are completely precipitated; 80% of the copper is precipitated as hydroxide by the excess base, this making possible the cheap removal of most of the copper and supplying the iron for the removal of arsenic and antimony in the acid leach; a large percentage of the zinc is separated from the residues and is contained in a clear settler overflow along with 20% of the soluble copper and all the soluble cadmium which goes to the purification plant, while the settler spigot product containing three parts of solids and two parts of solution is elevated to the acid leach.

The ground neutral classifier sand and the neutral settler spigot product are leached in three 10 by 20 ft. continuous leaching Pachuca tanks with the remainder of the cell acid and sent to the acid settlers. This operation is simple; it is necessary only to see that the overflow from the Pachucas is maintained at approximately ½% acid. Variations of 1% over a considerable time do not materially affect results, but too high an acid for a long period increases the volume of solution, hindering settlement, and causes the iron to circulate, which interferes with the settlement of the neutral side. Too low an acid for a long period results in low recovery due to undissolved ZnO and to high moisture in the filter-cake caused by precipitating ferric hydroxide, gelatinous silica, and alumina without granulating. Poor settling of the acid settlers also results for the same reasons.

The spigot product of the acid settlers, containing

60% solid and 40% moisture, goes by gravity to blanket-covered filters of the Oliver type. The cake from these filters is re-pulped with hot water or hot water and acid, in case there is enough acid-soluble zinc left in the first cake to justify it, and then re-filtered on a second set of blanket-covered Olivers to recover more of the soluble zinc. Hot wash water is used on each set of filters. If this double filtering operation is properly carried out, less than 20% of the zinc contained in the residues will be soluble in dilute sulphuric acid. In other words, if 90% of the zinc in the calcine was soluble, 10% of the total zinc in the calcine would be in the final residue as insoluble zinc and would be 80% of the total zinc in the residue. That is, the recovery would be 87½%. This is considered good practice and easily obtainable on 45% zinc calcine. The filtrate from the acid filters is combined with the acid settler overflow and goes to the copper roughing tanks, where scrap zinc from the tank room and scrap iron are added to rough out the copper. It is then pumped to the first of the neutral leach Pachucas and forms a part of the neutral leach acid.

The results of the acid leaching system are: (1) Solution of the remainder of the acid-soluble zinc and the copper; (2) final separation of the solids from the zinc and copper solutions; (3) roughing out of the copper and chlorine; (4) solution of sufficient iron to guarantee the removal of arsenic and antimony in the neutral leach step; (5) elimination of the arsenic and antimony which are only partly redissolved in dilute acid. About 10% of the arsenic and antimony circulate in the acid Dorr overflow.

Purification of Solutions.—The failure of early experimenters to recognize the harmful effects of minute quantities of certain impurities is the principal reason for their disappointment. It is not safe to say that a definite amount of any impurity such as copper, arsenic, antimony, cobalt, cadmium, tellurium, or selenium can be tolerated because the evil effects of most of these appear to be cumulative. For instance, when a small amount of copper is present (10 mg. per litre), the harmful effect of a little arsenic or antimony is greatly multiplied; therefore the only safe thing is to eliminate all to the greatest possible degree. If the neutral leach is properly carried out, the neutral Dorr overflow will contain, in addition to zinc sulphate, all the soluble cadmium and a certain percentage of the copper; but the arsenic, antimony, ferric iron, and part of the copper will have been precipitated. Final purification with zinc dust will take care of the copper and cadmium and will precipitate a certain amount of any arsenic and antimony that has passed the neutral leach; but it is not safe to depend on zinc dust for arsenic and antimony removal. The Great Falls purification plan is based on the fact that a large excess of zinc dust will completely precipitate the last traces of cadmium and copper; therefore, to get a reasonable efficiency from the zinc dust, a recovery system was installed and later supplemented by a purification slime-treatment plant. Copper is rapidly removed by the zinc dust, but cadmium is removed slowly and with difficulty unless a large excess of zinc dust is used. As cadmium must be reduced to less than 20 mg. per litre in the purified solution, to make grade "A" zinc in the tank room, and as no rapid test of which the authors are aware is sufficiently delicate to indicate that small amount of cadmium, it has been necessary to develop the present practice.

The overflow from the neutral settlers is pumped to twelve 10 by 20 ft. air-agitated Pachuca tanks, where it is treated; first, with recovered zinc sludge from the purification classifiers, to rough out the copper, then with zinc dust, added carefully until copper cannot be detected with the hydrogen-sulphide test. A definite excess of zinc dust is then added to ensure that all cadmium is precipitated. The amount of excess dust added is determined by practice and is varied from day to day by the zinc-plant superintendent after he has received the analyses of the neutral Dorr overflow and the purified solution for the previous day. It is a cut-and-dry method, but is not difficult to control. Like the rest of the process it must be carefully watched because an error here results in poor tank-room efficiency for several days. The best method is to avoid trouble by using plenty of dust. On the other hand, the use of too much dust is expensive, but so long as there is insufficient zinc sludge coming back from the classifiers to rough out the copper too much zinc dust is not being used.

After the addition of the excess zinc dust, the tank is agitated for 15 minutes and then discharged through a drag-line classifier to two 10 by 50 ft. Dorr settlers in parallel, which are in series with six 25 by 65 ft. concrete settling ponds. The ponds are arranged in parallel, so that any one can be cut out for cleaning without interfering with the others, and are 7 ft. deep at the feed end and 2½ ft. at the discharge; the sloping bottom facilitates cleaning. During normal operations one pond is sluiced out per shift; if the sludge is allowed to remain in the bottom of the pond too long, the cadmium oxidizes and goes into solution. Traces of acid or ferric sulphate hasten the re-solution of the cadmium. The pond overflow launder leads to a concrete sump, which supplies the feed to eight Shriver clarifying presses. The purified solution, after passing the presses, is as clear as crystal. If the overflow from the ponds is clear, the presses are probably superfluous, but they act as a safeguard, and all the solution has been forced through them. The clarified solution is pumped to two 12 by 50 ft. storage tanks and forms the feed to the tank room. The sludge from the purification Dorrs and the ponds is pumped to a scavenger Dorr, which receives all the spill and washings from the presses and the purification settling system and acts as a combination settler and slime storage tank for the purification slime treatment plant. The overflow of the scavenger settler is pumped back to the purification tanks. The spigot product of the scavenger settler is the feed to the purification slime treatment plant.

The scavenger spigot product is pumped to two 10 by 17 ft. leaching Pachuca tanks until they are about one-third full, then cell acid (10% sulphuric acid) is run in slowly while the tanks are agitated until copper begins to go into solution. At this point, the zinc and cadmium are in solution while the copper is still in the solid state. These leaches are now pumped to the copper settler, where the copper is collected in a rich slime, 30% copper in the spigot product, and is filtered on a 12 by 12 ft. Oliver filter and sent to the copper smelter. The overflow of the copper settler contains the cadmium and zinc and is run to two 10 by 17 ft. Pachuca purifying tanks, to which fine zinc dust is added in sufficient quantity to reduce the cadmium content of the solution to that of the neutral Dorr overflow. After the cadmium is precipitated, these tanks are discharged to a 10 by 30 ft. cadmium settler, the overflow of which goes back with the scavenger settler overflow for purification. The spigot product of the cadmium settler contains 12% cadmium and is to be treated for the recovery of metallic cadmium. Approximately 500 lb. of cadmium per day is contained in this product. The process for the recovery of cadmium has been worked out and the plant will, most probably, be installed when the demand for cadmium justifies it.

(To be continued).

HEAT TREATMENT IN SHARPENING DRILL STEELS.

In the *Mine and Quarry* for April, J. A. Noyes and J. M. [illegible] discuss the scientific principles underlying the heating of drill steels prior to sharpening. It is becoming generally recognized that the rule of thumb methods usually followed in the mine-drill sharpening shop must be supplanted by a systematic yet practical application of known facts about the physical properties of high-carbon steel. This article makes a few practical suggestions regarding the proper heating, forging, and tempering of high-carbon drill-steel.

In the discussion of the proper forging and tempering temperatures, it is first necessary to understand what is meant by the critical point of the steel. The critical range can be ascertained by watching the slow heating of a piece of steel in the furnace. The steel brightens in colour with the rising heat of the furnace until a point is reached where the steel apparently becomes a trifle darker and cooler than the furnace. If the heating continues, the steel again increases in brightness, once more assuming the same brilliancy and temperature as the furnace. The darkening is due to the absorption of heat and the temperature at which this absorption takes place is known as the decalescent or critical point. At this point the ferrite and pearlite are converted into austenite. If the furnace is now allowed to cool slowly, a point will be reached where the steel remains visibly brighter than the furnace, but in a few seconds it again assumes the colour of the furnace and darkens with it. This brightening of colour is due to the throwing-off of heat and is the recalescent point, where the austenite changes back to ferrite and pearlite. The decalescent point on the rising heat is at a higher temperature than the recalescent point of cooling. For practical purposes, the critical point is the decalescent point, and the critical range includes the temperatures just above the critical point. The critical point of steel is different for steels of different carbon contents. For drill steel averaging 0·60% to 0·90% carbon, the critical range is from 1,420° to 1,350°F. By coincidence this steel becomes non-magnetic at a temperature which for all practical purposes is the same as the critical temperature of the steel. This fact therefore affords a simple, easy method of determining the critical point of any drill steel regardless of its carbon content. By bringing the heated drill bit up close to an ordinary horse-shoe magnet, it can be determined whether or not the temperature of the bit is above the critical range of the steel by merely noting whether or not the magnet is attracted by the hot steel. If the magnet is attracted, the temperature is below the critical point. If it is not attracted by the steel, the critical temperature has been passed.

The structure and physical properties of the drill bit depend on the temperatures used for heating the steel preceding both forging and quenching, as well as on the care exercised in the mechanical working or forging of the bit. The finest grain size obtainable exists just as the steel passes through the critical range on the rising heat. Further heating above the critical temperature coarsens the grain, and this coarse structure remains in the steel if it is allowed to cool undisturbed. If, instead of allowing the steel to cool undisturbed, it is vigorously hammered, the coarse crystalline structure can be broken up and the grain refined. If, however, the hammering is stopped above the critical range, the coarse crystallization sets in again, and the higher the temperature above the critical range at which the forging stops, the coarser the structure will be. The finishing temperature for the forging operation of the drill-steel bit should therefore be at or slightly above the critical temperature, and the forging should be by rapid, vigorous hammering and not by "bulldozing" or "squeezing." It is a well-known fact that hammered forgings command a much higher price than drop forgings, where the metal is literally pressed into shape at high temperatures. The forging operation should not continue below the critical range, because cold working below this heat causes distortions and internal strains, which result in brittleness and in steel breakage.

Heating in a coal forge is unsatisfactory, as the abundance of oxygen required for the combustion of the coal gives a heavy oxidizing flame, causing excessive scaling of the steel. Coke is only slightly better as a fuel. With both coal and coke furnaces, it is almost impossible to get a close regulation of temperature. In heating steel, it expands, except in passing through the critical range, at which point it contracts. Therefore, if a piece of cold steel is thrust into a raging hot fire, the outer surfaces are passing through the critical range and are contracting, whereas the centre of the bit is still expanding, having not yet reached the critical temperature. This causes cracking and checking of the steel. In the same way, even if the steel is not thrust directly into a raging open fire, but is only inserted directly into the combustion chamber of a furnace, where the extreme high temperature flames are allowed to impinge directly against the drill bits, this same condition will result, and either cracking or checking of the bits takes place. It is a well-known fact that if the higher carbon steels are allowed to remain in a hot furnace for any great length of time the carbon is precipitated in the form of graphite, and when this occurs, the steel is greatly reduced in efficiency, even if not entirely ruined. It is common practice in drill-sharpening shops for the smith to allow the drill steel to remain in the furnace while making adjustments on the drill-sharpening machine, changing dollies, or making minor repairs, and this is sure to prove costly in the end, as the outer surface of the steel becomes decarbonized and will not respond to the same heat treatment that is effective before the soaking takes place. This soaking also increases the coarseness of tructure, as coarseness of structure not only increases with high temperatures, but also with the length of time for which the steel is held at the high temperature. The maximum temperature for forging drill steel should not exceed 1,650° to 1,750°F. Temperatures higher than this coarsen the structure to such an extent that even the thorough hammering during the forging operation cannot again refine the grain. The result of too high a forging heat is checked, cracked, and brittle bits, irrespective of what the subsequent tempering treatment may be.

In tempering all drill bits, quenching should take place at the critical temperature or at about 50°F. above this point and on a rising heat. When quenching takes place at this temperature, maximum density and toughness, with maximum hardness, are secured. The heating preceding the quenching should be slow, uniform, and thorough, and at the lowest possible temperature that will secure the desired results. The furnace temperature should be slightly above the critical point of the steel to compensate for some loss of heat while transferring the steel from the furnace to the quenching bath. Heating for quenching cannot be done satisfactorily in a coal or coke furnace, where close regulation of temperature is impossible. Overheating is the cause of 90% of the bad results from

drill steel. Unfortunately many practical smiths still believe in the efficiency of high temperatures for greater hardening effect. While to a very limited extent it may hold true that the higher the temperature the harder the steel, the questionable gain in hardness is more than offset by increased coarseness in the grain of the steel, and by internal strains, both resulting in faster wear on the bits, and more breakage. Heating for hardening requires great care. The rapid quenching of hot steel is the most severe test that steel can be put to. If the heating is not uniform, it naturally follows that the bit after quenching will be subjected to severe internal strains. Hardening cracks are therefore more often a result of improper heating than of any defect in the steel.

To emphasize the importance of quenching steel at the lowest possible temperature and still be above the critical point, the authors cite a test that was made on two gears that were machined from the same bar of steel, and given identically the same heat treatment, with the single exception that gear B was quenched at a temperature 50° higher than gear A. Both gears showed the same degree of hardness. While it required 48 blows of a 10 lb. hammer dropping 30 in. to break a tooth out of gear B, it required 200 blows of the same hammer falling the same distance before a tooth could be broken out of gear A. This difference of only 50° lower quenching temperature resulted in 400% increase in toughness. This example clearly illustrates that in order to get the maximum wear-resisting qualities in a drill bit, the quenching should be at the temperature at which the magnetism leaves the steel, and thus theory and practice both support the old rule that the lowest temperature that gives the desired results is the best temperature.

One of the conditions that works a hardship on the drill smith in the average drill shop is having to handle steel which contains varying percentages of carbon. Steel containing 0·90% carbon does not require as high a temperature for hardening as a piece which contains 0·50% carbon. If both steels were quenched at a temperature suitable for the higher carbon steel, the other steel having a lower percentage of carbon would be too soft. If the quenching temperature is raised high enough to secure the proper hardness of the 0·50% carbon steel, and if the steel with the higher carbon content is quenched at this higher temperature, breakage and chipping of the bit is practically certain. This may cause the blacksmith a great deal of trouble, as in one section of the mine there may be a complaint about the steel being too soft, while other sections of the same mine will report the steel as being too hard.

The authors describe an inexpensive electrical indicator for determining when the steel has reached the decalescent point. This is an ordinary horse-shoe magnet hung from a fibre or other non-conducting support. At the upper end of the support is a copper contact for closing an ordinary light circuit. This indicator is more serviceable in the shop than an ordinary horse-shoe magnet hung from a cord. When the heated bit is pressed against the copper plate the light will flash if the steel is at too low a temperature for quenching. The correct heat for quenching is when the magnetism leaves the steel. This indicator gives one of the two necessary facts about the temperature of the steel for quenching. It is the fact that the steel is hot enough, having passed the critical temperature. The second fact that must be known is that the temperature is not too high. This can be assured by using an oil or gas furnace, the maximum temperature of which is indicated by a pyrometer. If the maximum temperature of the furnace is maintained at a predetermined point, there will be no danger of overheating the steel, irrespective of the time the steel remains in the furnace, within reasonable limits. In the past it has been the general practice to insert the drill bits into a raging hot furnace and depend on the watchfulness and skill of the operator to judge when the proper temperature has been reached. Naturally the results have varied with different men, different light conditions, and with the conglomeration of steel of several makes, and various chemical compositions.

When the proper temperature is secured, quenching should be rapid. The object of quenching is to retain the characteristics which the proper heating has developed. The most satisfactory quenching medium for drill steel is circulating cold water. For uniform results the temperature of the water should be kept fairly constant. The effectiveness of water as a quenching medium falls off rapidly above 100°F. Brine solution is a faster quenching medium than water, but its effectiveness decreases with increased temperature, particularly where large quantities of steel are handled. Oil is used as a quenching medium where a high degree of hardness is not necessary.

The design of a safe, efficient drill-steel furnace is an engineering problem, and it must be treated as such. A drill-steel furnace must operate at different temperatures, as the degree of heat required for hardening is different from that required for forging. The temperature control must be accurate at different heats. Consideration must be given to the time required for heating. The part of the steel to be heated must be considered; for example, a short heat at the end of the steel when tempering bits or a forging heat at a point five inches from the end when forming lugged shanks. Fuel consumption cannot be treated by itself. It involves proper and complete combustion of the fuel as well as the results desired. The heat developed must be used and not wasted. The authors proceed to give details of the Sullivan drill-steel furnace. This is a low-pressure oil or gas furnace of the underfed type. The combustion chamber is located below the adjustable hearths. The slot width between the hearths can be varied from ½ in. to nearly the full width of the combustion chamber. This permits heating the bar of steel with any length of heat and at any point along the bar. This is a particularly valuable and serviceable feature in forming collared or lugged shanks. At the hot end of the furnace is a thermo-couple which registers the temperature in connection with a pyrometer indicating apparatus. The temperature at the point where the drill bits are withdrawn from the furnace can, therefore, be kept at any predetermined point by regulating the fuel supply, thus maintaining the desired heat as indicated by the pyrometer. For example, in heating the steel for quenching, the pointer on the instrument may be set at 1,450°F. When the temperature in the furnace at the point of withdrawal of the steel, which is where the hot end of the thermo-couple is located, is at 1,450°F., a white electric light will burn. If the temperature increases 25° the white light goes out and a red light comes on. If the temperature drops 25° below the figure at which the pointer is set, a green light burns. In heating for forging the pointer on the instrument can be set at a higher temperature, for example, at 1,650°F., and the three coloured electric lights again operate to indicate correct, high and low temperatures. In this furnace the combustion of the fuel takes place below the hearths in the combustion chamber. When the furnace is up to heat, the combustion chamber, hearth pieces, and the adjustable brick stop become incandescent and the drill bits are heated by an indirect or reflected heat. Oxidizing or scaling of the surface

of the bits is thus prevented. The steel cannot be inserted directly in the combustion chamber. The steel cannot be overheated, as the maximum temperature at the hot end of the furnace is a safe heat and is checked with the pyrometer. The length of heat on the steel can be kept short by narrowing the width of the slot between the hearths. In the normal operation of this furnace, it is kept well filled with steel, practically closing the slot opening from the combustion chamber, resulting in increased fuel economy. The cold steel is put in at the burner end, which is the cold end of the furnace. As the heated steels are withdrawn at the other end, the others are rolled along toward the hot end, so the heating is progressive, slow, uniform, and thorough. Overheating of the steel is impossible. Although the construction of this furnace is comparatively simple, the exact proportioning of the combustion chamber, the location and height of the hearth and hood pieces, the type and position of the burner, the details of the adjustable drill rest, have all been arrived at by a development process under actual working conditions.

Globe & Phœnix Metallurgy.—The January *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa contains a paper by V. E. Robinson on the present method of treatment of the ore at the Globe & Phœnix gold mines, Southern Rhodesia. It will be remembered that an article by H. T. Brett was published in the MAGAZINE for July, 1911, but the methods there described have been largely superseded.

An analysis of the ore given by Mr. Brett is as follows: SiO_2 and insoluble, 76·32 %; Sb, 0·73 %; Fe, 2·58 %; S, 0·96 %; CaO, 1·21 %; MgO, 0·44 %; As, trace; Cu, trace. The amount of antimony, however, varies considerably. Screen samples, taken over a period of three weeks, have contained as much as 2·39 % Sb and 0·26 % As, while the massive stibnite removed by sorting contains up to 80 % Sb_2S_3. Much of the gold present in the ore is free, and easily caught on amalgamated plates; some of it is coated, but can be amalgamated in grinding pans; and some escapes the pans but can be retained on canvas strakes. Owing to the stibnite present, and also possibly to ferrous iron, the tailing cannot be treated directly by cyanide, but if it be allowed to partly oxidize by weathering, it becomes amenable to cyaniding. After breaking and sorting, the ore is wet-crushed by stamps and passes over amalgamated plates to grinding pans. It then flows over canvas strakes to a classifier, which separates sand from slime. The sand is discharged to the dump, and the slime to dams. Both products are allowed to oxidize by weathering, after which the sand is ground in tube-mills in cyanide solution, and treated by counter-current continuous decantation, while the slime is treated by the ordinary decantation method.

The author proceeds to give details of the processes. The ore is trammed from the shaft bin, and dumped on steel grizzlies, with 1½ in. openings and set at an angle of 50°. The oversize is fed to two 15 in. by 9 in. Blake-Marsden breakers, whence it is conveyed by belt to a screening and washing trommel. Fines go direct to the mill bin; the remainder, before entering the bin, is fed on to a sorting belt, where waste rock and stibnite are removed, and discharged to their respective dumps. About half a ton of massive stibnite is sorted out per day. The greater portion of the stibnite remaining in the ore is present in the fines.

The mill is equipped with 40 stamps of 1,250 lb. weight, using 200 mesh screens (200 holes per sq. in.), with a drop of 8½ in., and making 108 drops to the minute, the stamp duty being 5·75 tons per day. From the mortar-boxes the pulp flows over eight amalgamated copper plates, 12 ft. in length, of which the lower 4 ft. is covered with blanket. From the plates the pulp passes to twelve 5 ft. grinding pans, to which mercury is added. These pans run at 48 r.p.m. Their shoes and dies are made on the mine, a set lasting on an average 60 days. The pan discharge passes over canvas strakes, then through three mercury traps to a large launder designed as an auxiliary mercury trap, thence to the tailing pump. This auxiliary mercury trap consists of a wide launder having several layers of heavy screening (½ in. aperture) fastened to the bottom. The strakes cover a rectangle 19 ft. long by 53 ft. broad, and are stepped in the centre. The strake product is reconcentrated over a small strake, the discharge of which passes back into the grinding pans. This concentrate is very fine, so that during barrel treatment it is mixed with coarse river sand, and a few tube-mill pebbles. To promote efficient amalgamation a little sodium cyanide is added, which acts as a desulphurizing agent, keeping the mercury clean. It dissolves no gold. From 65 % to 70 % of the gold content of the ore is recovered by amalgamation, of which 60 % comes from the plates, 13 % from the blankets at bottom of plates, 19 % from the pans, and 8 % from the canvas strakes. The width of the strakes is of more importance than their length, and if, through insufficient space, their width must be curtailed, it will be found advantageous to install step tables, with a drop every 6 ft. The fall should be 1½ in. per foot, and a convenient size for each strake is 30 in. wide. The blankets should not be more than 36 in. long, this length being handled easily. Canvas is superior to blanket in saving fine gold. When first discharged both sand and slime have a dull bluish-grey appearance, but as oxidation proceeds this changes to a yellowish colour.

The capacity of the sand plant is 300 to 320 tons per 24 hours, and an extraction of 75 % to 80 % of the gold content is obtained. Grading analysis of dump sand before regrinding shows:

Mesh	%
+ 30	5
– 30 + 60	24
– 60 + 90	25
– 90 + 150	18
– 150	28

Different sections of the sand dump, however, vary a great deal, and the sand now being discharged from the mill contains only 25 % of + 90 mesh after regrinding, the residue grading showing about 15 to 20 % of + 150 mesh. The tube-mill pebbles used are obtained from adjacent river beds. Waste rock has been used, but is inferior to these pebbles. The cyanide strength is kept at about 0·03 % KCN in the tube-mill circuit and agitators; 1·1 lb. cyanide and 0·2 lb. lead nitrate are consumed per ton. The sand is conveyed from the dump to the treatment plant by mechanical haulage.

The dams for accumulating the current slime occupy an area of about 5 acres, divided into three separate portions, each being 6 ft. deep, so that, while one is being filled, another is full awaiting treatment, and the third is under treatment. When a dam is full, it is allowed to dry sufficiently to hold the weight of the oxen and plough. The whole surface is then ploughed over several times, at intervals of five to six weeks. When treatment is commenced on a dam, half the ploughed area is removed to a depth of 14 in., and taken to the treatment plant. The rails are then shifted to the other half of the ploughed area, which in its turn is treated, and while treatment of this second half is proceeding,

the first half is reploughed several times. This procedure is continued until the dam is exhausted. The ploughed and oxidized slime is trammed by oxen to a vortex mixer. The cyanide treatment is carried out in circulation and decantation tanks, circulation and transfer being effected by pumps. The cyanide consumption is about 1·6 lb. per ton treated. An extraction of close on 80% of the gold content is obtained.

Precipitation on the whole is good, although the zinc is apt to become plated with gold. The solution from the sand treatment plant gives far less trouble than that from the slime plant, and the products of the two plants are kept separate throughout clean-up and smelting. In the slime boxes, a varying amount of copper is precipitated in the lower compartments. The smelting equipment consists of a paraffin oil-fired tilting furnace, taking a No. 400 crucible; three coke furnaces; one two-tray calcining furnace, and a retort. Slags and other by-products are treated in a Taverner furnace. The retort is of the usual design. A small amount of antimony present in the amalgam causes objectionable fuming when taking sponge from retort, and also makes the gold very brittle. After the precipitate from the sand plant is smelted, it is refined by re-melting with an oxidizing flux in clay-lined pots, skimmed, and a blast of dry compressed air allowed to play on the surface of the molten metal for from one to two hours. The iron pipe, ½ in. diameter, delivering the air, is kept about 4 in. from the surface of the metal, and just sufficient air is turned on to give a faint ripple over the surface; antimony, and other easily volatilized metals come off in dense fumes until completion of the operation. The bars are cast under a borax cover, and assay over 800 fine. The slime bullion requires different treatment owing to the large amount of copper often present. It is granulated, mixed with sulphur, and heated slowly in a graphite pot. Most of the copper and other base metals, as well as part of the silver, enter the matte, but antimony is not entirely removed. After the charge has been fused, poured, and the matte removed, the bullion obtained is re-melted in a clay-lined pot with an oxidizing flux, then skimmed and toughened by compressed air. The matte is crushed fine, mixed with an equal weight of borax, and quarter its weight of crushed cyanide, and heated in a graphite pot until all action ceases. The matte is now decomposed, and practically all the gold and silver are recovered as fairly good bullion, which is further refined by oxidation, and is then included with the bullion obtained from the sulphur treatment.

A considerable amount of experimental work has clearly demonstrated the desirability of weathering before treatment. Tests quoted by the author show a recovery of 84·2% and a consumption of 1·5 lb. cyanide per ton with weathered sand, and 60·5% and 2·8 lb. with current sand. The period required for oxidation varies according to conditions. The slime might remain in the dams for years, without any visible change taking place, but as soon as it is ploughed, and thus exposed to the air, the change to a yellowish colour commences. Under the best conditions, slime will oxidize sufficiently for treatment in about 20 days. Under working conditions each half of a dam will receive two ploughings in approximately six weeks. As a general rule, the sand will be on the dump over six months before it is treated, though under favourable conditions, such as small bulk, it would be ready for treatment in a much shorter period. Occasionally, when the antimony contents are low, a fairly good extraction may be obtained without preliminary oxidation by weathering. The use of a certain amount of lime in treating the oxidized material is desirable, as it decreases the cyanide consumption, but too much is fatal to a good extraction.

Calcium.—At the meeting of the Institute of Metals held in March, P. H. Brace presented a paper on calcium, its history, properties, and manufacture. We give here a brief abstract.

Sir Humphry Davy appears to have been the first to isolate traces of calcium by the electrolysis of moist lime; though while Davy's work was in progress he received a letter from Berzelius and Pontin which described the results of their experiments on the electrolysis of the alkaline earths with mercury cathodes. Davy repeated these experiments and secured amalgams of calcium and the other alkaline earths, confirming the conclusions of Berzelius and Pontin. In 1854 Bunsen prepared small quantities of calcium by electrolysing an aqueous solution of the chloride with a mercury cathode and subsequently distilling off the mercury. Matthiesen, in 1856, prepared small quantities of impure metallic calcium by the electrolysis of a fused mixture of strontium chloride and calcium chloride. Comparatively little interest was shown in the subject until Moissan, in 1898, published his results which showed that nearly pure calcium could be prepared by the reduction of calcium iodide by means of sodium. In the same paper Moissan mentions the electrolytic preparation of calcium from the fused iodide. In the same year he published an extensive list of the properties of the calcium prepared by the sodium reduction method. In 1898 Bela von Lengyel gave an account of the properties of calcium prepared in a cell with a porous diaphragm. Borchers and Stockem described a calcium cell in which the metal was deposited in the form of a sponge on a water-cooled cathode projecting upward from the bottom of the cell submerged in the electrolyte of fused calcium chloride. A similar cell was used in 1903 by Goodwin, but he operated at a higher current density and temperature, and so caused the calcium to collect in the molten state and rise to the top of the bath, whence it was removed by means of a ladle. Shortly after this, in 1904, Rathenau made the next noteworthy advance when he used a cathode which just touched the surface of the molten electrolyte, and operated it at such a current density that the surface of the calcium in contact with the electrolyte was kept molten. The cathode was gradually elevated as the metal accumulated, and an irregular rod was thus built up. This method was commercially successful. Goodwin, in 1904, published the results of extensive experiments with an apparatus of the Rathenau type, and gave an account of the physical properties of the calcium he had prepared. In 1905 Wohler reported on his experiments in which an electrolyte containing 100 parts of $CaCl_2$ and 17 parts of CaF_2 was used. He believed that the low melting point of the above mixture was an advantage, but the experience of others has since indicated that there are disadvantages which more than outweigh the convenience of the low melting point. Arndt described the preparation of calcium-aluminium alloys by the electrolysis of calcium chloride with an aluminium cathode. Alloys containing between approximately 20 and 80% of calcium are described, but no particularly useful properties are mentioned. In 1909 Frary and Badger published a comprehensive bibliography of calcium metallurgy, followed by a description of the results of their work with the Rathenau form of cell, and in the following year, Frary, Bicknell, and Tronson discussed the efficiency of the apparatus just mentioned, and concluded that practically 100% current efficiency could be obtained by proper manipulation. They were of the opinion that pure calcium chloride made a more satisfactory electrolyte than the

calcium fluoride-calcium chloride mixture of Wohler. At the same time Johnson published an account of a series of experiments with the submerged cathode cell of Borchers and Stockem, and the Rathenau cell, and described the development and operation of a novel apparatus in which the metal was deposited on a perpendicular, vertically-moving iron ribbon cathode which closed the narrow end of a V-shaped enclosure containing the electrolyte. The wall of the enclosure opposite the ribbon was of graphite, and formed the anode. The cathode current density was kept considerably lower than in the case of the Rathenau cell, and it appears that the calcium was deposited in the solid state, producing a thick plate on the iron ribbon in much the same way as metals are ordinarily deposited from aqueous solutions. In 1909 Cowper-Coles patented a process for the electrolytic preparation of calcium and similar metals, the principal feature of which was the use of a cathode in the form of a disc whose edge just touched the surface of the electrolyte, and which was rotated as the deposit collected. In 1911 a refining process was described in a French patent, which had in view the elimination of the included chloride and other mechanically held impurities from calcium produced by the Rathenau and similar methods. In this process the calcium was melted under calcium chloride and collected under an inverted conical iron bell submerged in the molten chloride. The idea was that the calcium would separate completely from the chloride and other impurities by virtue of the differences in their densities. Moldenhauer and Anderson, in 1913, described experiments with mixed fused electrolytes in which calcium alloys with zinc and some other metals were produced. In 1920 the writer (Mr. Brace) published a short account of some experiments on the electrolytic production of calcium, and described a new type of cell.

Of the properties of calcium, the most important are its low specific gravity, 1·548, and the fact that it decomposes water. The list of calcium alloys that have been prepared and investigated is large. The outstanding general properties seem to be brittleness and the tendency to the formation of intermetallic compounds. Very few of the calcium alloys appear to have any usefulness as structural materials. Aluminium-rich alloys may find application because of their slight advantage in weight over pure aluminium. Lead alloys containing calcium and other alkaline earth metals are finding application as bearing metals for service such as the usual white metals are put to. Barr has published the results of an extensive investigation of the properties of a number of calcium alloys by the method of thermal analysis. Calcium was alloyed with thallium, lead, copper, and silver, and in every case definite evidence of the occurrence of intermetallic compounds was secured. Moldenhauer and Anderson investigated the direct production of calcium alloys from fused mixed electrolytes. Zinc, aluminium, and potassium alloys were prepared. Cooper has patented alloys of calcium with aluminium, in which the calcium content may be as high as 8%. The claims make a feature of lightness, ductility, and ease of machining. Kroll has patented the use of calcium and its light alloys as a filling for hollow steel structural members. He has claimed that, as compared with nickel-chromium steel, structures made according to his patent have the same strength with but 41·56% of their weight. Hirsch and Aston experimented with the production of iron alloys, and state that up to 6% of calcium may be alloyed with iron by reducing Fe_2O_3 in gas-tight iron cylinders. They state that calcium destroys the welding property of iron. Watts and Breckenridge used the brittle alloys of calcium with aluminium, silicon, and manganese as reducing agents in the course of experiments on the preparation of some of the more difficultly reducible metals. The brittleness of the alloys was found a great convenience, as it enabled them to be pulverized and brought into an intimate mixture with the substances to be reduced. Stockem stated that calcium dissolved in cast iron with the evolution of considerable heat, and that if considerable amounts of calcium were added a scum of calcium carbide collected on the surface of the molten metal. He also stated that calcium alloys with copper in all proportions, and that some of these alloys are useful as deoxidizers and scavengers in non-ferrous alloys. Watts found that calcium acted as a powerful desulphurizer of molten low-carbon iron, but that the effect on the phosphorus content was relatively small. Hackspill prepared lead alloys by the reduction of lead chloride with an excess of calcium. The alloys were harder and less brittle than lead and tarnished in the air. They were slowly attacked by cold water, and more rapidly by hot water. A crystalline alloy, Pb_3Ca_2, was isolated by distillation *in vacuo*. A summary of the more important uses of metallic calcium is as follows: (1) As a reducing agent in the preparation of metals and alloys from their oxygen and halogen compounds. (2) As a reagent in the purification of the inert gases. (3) As a scavenger in non-ferrous metals and alloys. (4) As a scavenger, decarburizer, and desulphurizer of ferrous alloys. (5) As a dehydrating agent, as in the treatment of oils and alcohols, for example. (6) As a means of fixing atmospheric nitrogen. (7) As a source of pure calcium carbide by direct reaction with pure carbon. (8) As a stiffening filling for hollow metal structural members. (9) As a constituent of a light aluminium alloy having useful properties. (10) As a hardening component in certain lead-base anti-friction alloys.

There are three general methods for the preparation of calcium, as follow: (1) By the reduction of calcium compounds by metals of the alkali group. (2) By the electrolysis of concentrated aqueous solutions with a mercury cathode. (3) The electrolysis of fused halogen compounds of calcium. Of these three methods the last is by far the simplest and most direct.

Fire-Damp in Gold Mines.—During the last few years there have been a number of fire-damp explosions in gold mines in the Far East Rand, notably at Brakpan, Government Areas, and Daggafontein. The general supposition is that the fire-damp has its origin in the Coal Measures several thousand feet above the reef. A paper on this subject was read by T. N. Dewar at the February meeting of the Chemical, Metallurgical, & Mining Society of South Africa. We quote from this paper two instances of accidents that have occurred at Brakpan.

In the Brakpan, the first accident happened in No. 2 shaft section, on March 19, 1913. The No. 8 West winze dipped at an angle of 15° to 20° for 270 ft., and then rose gently for 130 ft. Two small dykes were passed through, one on the slope and the other up the rise. A fissure was encountered at the face from which a large quantity of water issued, and the winze became partly flooded. A pump was installed to handle the water. As the water-level fell suddenly a pumpman went down to ascertain the cause and found the water had fallen about 4 in. from the hanging in the hollow. On holding his lamp up to make the inspection, an explosion occurred and he sustained fatal injuries. Later on it was ascertained by tests that the gas issuing from the fissure was fire-damp. The gas had accumulated behind the water in the hollow and was released by the lowering of the water-level to the pump. The depth from the surface to the face of the winze was about

3,470 ft. On August 26, 1915, the fire-damp was met with in a different part of the same mine. In going through with a cross-cut in the 17 East-level an upthrow fault with a 70 ft. throw was encountered. It was intended to put up a boxhole from the 17th to the 16th levels, so a rise 9 ft. by 7 ft. was started at a slope of 30° and struck the fault at about 30 ft. up. Continuing through the foot-wall shales at an angle of 60° the rise reached a length of about 120 ft. A slight trace of fire-damp had been met with on July 13, 1915, and a native was burnt, so ventilation had been provided for by 6 in. galvanized iron piping and a fan. Despite this, more gas came off and an accident happened on August 26, whereby the trammer and a native were seriously burnt, the latter succumbing to his injuries. Apart from the fault there was no fissuring in the shales and the place was dry. The depth from the surface to the scene of the accident was a little over 4,000 ft.

The author proceeds to give an explanation of the presence of the fire-damp. Looking at the geology of the country in the neighbourhood of the mines mentioned, it is found that basins of coal-bearing Karroo rocks overlie the dolomites, which in turn overlie the Witwatersrand series. In several of the shafts the dreaded "Green Dyke" is found, a dolerite sheet which weathers and gives great trouble with pressure on the timbers. It occurs in the No. 1 and No. 3 shafts, Springs Mines, No. 1 and No. 2 shafts, Daggafontein, and attains its greatest thickness of 95 ft. in the South shaft of the New State Areas. A syenite sheet split up into several sections appears in most of the shafts in the south and east of the Far East Rand. At No. 2 shaft, Springs Mines, it totals 220 ft. in two sections. Interbedded in places with the syenite sheet is the dolomite, which attains its greatest development in four sections at Daggafontein No. 1 shaft, where it has a thickness of 436 ft. The Coal Measures are in the form of basins of very varying thickness. Taking an average of eleven shafts situated in Brakpan, Government Gold Mining Areas, New State Areas, Springs, and Daggafontein, the average thickness to the base of the Dwyka conglomerate is 148 ft. In this area the coal seams average 19 ft. in thickness, and attain their greatest development in a line running south and east of the gold mines. The seams have been or are being worked at Apex, Brakpan, Rand Colliery, Schapenrust, and De Rietfontein, a belt of 13,000 yards long. Brakpan colliery was worked over the present Brakpan mines, but the other collieries have no gold mining going on at present underneath them. At De Rietfontein colliery, when it was working, bubbles of fire-damp were sometimes found issuing from the foot-wall. Though the Coal Measures are well developed in the three shafts of the Springs mines, no fire-damp has been found in that mine, which will probably in time work under the abandoned De Rietfontein colliery. Taking the three mines particularly concerned in this paper, the Brakpan No. 2 shaft has a 14 ft. seam of coal in the 144 ft. of Karroo rocks. The Government Gold Mining Areas, the south-east shaft, has no coal in 90 ft. of sandstones. The Daggafontein No. 1 shaft showed no coal in 72 ft. of sandstones, but the No. 2 shaft, 2,000 yards to the west, had 50 ft. of inferior coal in 175 ft. of Measures. The surface elevations show that the coal has been denuded at No. 1 shaft near the Blesbok Spruit. At the Largo colliery, where a little fire-damp was found recently, the development of the Coal Measures is typical. There are three seams of coal, totalling 34 ft. in a thickness of 193 ft. Gas has only been met with in the lower seam, which has a thickness of about 10 ft. It is overlain by a dense close-grained shale of about 8 ft. All the strata above this dense shale are porous, and no gas is found in the two upper seams. The lower seam referred to overlies 3 ft. of Dwyka shales which rest on the Dwyka conglomerate.

It is noticeable from the occurrences described that the fire-damp in the mines of the Far East Rand is found principally in the presence of upthrow faults which bring the foot-wall shales into position for driving through. In the majority of cases, faulting and water seem necessary for the presence of gas. In some cases sulphuretted hydrogen accompanies the fire-damp, but not always. It is assumed by many people that the gas travels with the water down fault planes from the Coal Measures. The great problem is to account for the vertical movement of the gas of nearly 4,000 ft. In the Apex old colliery a little fault came through on the east side of the shaft. This was about 1896, and a good supply of water came off the fault. A sump was made and an electric pump installed to raise the water to the surface for boiler and domestic use. The workings of the colliery steadily progressed away from that area, and the supply remained undiminished. Some water overflowed into the abandoned workings near the shaft and remained there for years. About 1906 the Brakpan mines began to develop from the No. 2 shaft, 1,500 yards distant. As the drives came forward toward the Apex, the spring suddenly disappeared, and the water in the workings followed suit. It would, therefore, appear that in places there is a definite connection through faulting from the Coal Measures to the gold zone. The dolomites form a very convenient water channel all over the area. They are jointed and large quantities of water lie in the crevices. For instance, during cementation work at Brakpan No. 3 shaft, small plates of cement were found in sinking through the dolomite in the south shaft of the New State Areas 3,300 yards away.

The difficulty is just why fire-damp should not take the line of least resistance and escape up the faults to the surface, instead of travelling down them. The fact remains that fire-damp is generally found in mines where the Coal Measures are developed above or where a connection with them is available through the dolomites for gas to travel. On the other hand it is to be noticed that the gas is usually found actually in or about the foot-wall shales which are very jointed. Carbon is also found occasionally on the contact of the reef and the shale where, especially if associated with pyrites, a great enrichment of values takes place. Perhaps under heat and pressure some reaction may take place between the pyrites, water, and carbon in or under the shales to produce something in the shape of fire-damp.

Redmayne, in the "Ventilation of Mines," states that a blower of fire-damp has occurred from time to time in the Van lead mine, near Llanidloes, in Montgomeryshire, the vein of which traverses rocks of the Lower Silurian age. It is difficult to account for the presence of fire-damp at this mine as there are no Carboniferous rocks in the neighbourhood, and decaying timber could not account for the existence of a blower of gas. Possibly it owes its origin to the decay of plant or animal life of the Silurian period, and has been pent up through the succeeding ages, or it may be due to the chemical action of acidulated waters or mineral substances. It is a peculiar feature of the emissions at this mine that they are accompanied by sulphuretted hydrogen.

The difficulty in connection with occurrences of fire-damp in metalliferous mines is the fact that very few of the men working there have any knowledge of fire-damp. It constitutes a danger when it comes in contact with people who have not even heard of it. Its presence is often first announced by fatal burning accidents. In these deep mines the temperature of the workings is

generally fairly high, about 75° to 85°. European and natives alike work with a minimum of clothing, and when an accident happens, the burning is severe owing to the amount of skin exposed.

Trevorite. In our issue of August, 1920, brief mention was made of a new discovery of nickel in South Africa, the mineral being apparently a new one. At the February meeting of the Chemical, Metallurgical, & Mining Society of South Africa, Andrew F. Crosse exhibited the mineral, which assays as follows:

	%
Nickel Oxide	[illegible]
Iron Oxide	[illegible]
[illegible]	[illegible]
Calcium Oxide	0·20
Silica	[illegible]
Loss on ignition, chiefly water	15

The metallic nickel content is 29·6%, and metallic iron content 35·7%; platinum was present in the sample to the extent of 0·2 dwt. per ton. Mr. Crosse also exhibited an alloy of iron, containing 52% nickel, made by smelting this ore. There is no arsenic or sulphur in the mineral, and the crude ore can be concentrated on tables or magnetically. Mr. Crosse proposes to name the mineral "trevorite," after T. G. Trevor, Mining Inspector for the Pretoria and Barberton districts. Mr. Trevor proceeded to give some account of the occurrence. The deposit is found on the Lily line in the Jamestown Series, just opposite Sheba Bridge, Barberton district. Particulars were given in the short article in August last, as already mentioned.

The Mackenzie Oilfield.—At the meeting of the Institution of Petroleum Technologists held on April 27, Dr. T. O. Bosworth read a paper on the recently discovered oilfield near Fort Norman on the Mackenzie River, in the North-West Territories of Canada. Dr. Bosworth was engaged a few years ago in geological investigations in connection with oil in this part of the world. The new oilfield is the most northerly of the prospective fields then examined, and the flowing well recently brought in is No. 1 test-well located during his expedition seven years ago.

Within the region discussed by Dr. Bosworth in the present paper petroleum appears to have been first recorded about a century ago by Sir John Franklin, who saw, near Bear Mountain, "sulphurous springs and streams of mineral pitch." Also, for the past fifty years or more, a "tar spring," far inland from the river, has been known to the Hudson Bay Company's men at Fort Good Hope, who have utilized this seepage oil for tarring their canoes. In 1887 an exploration of the Mackenzie Basin was made by R. G. McConnel, who reported in the Annual Report of the Geological Survey of Canada, 1888–9, the occurrences of bituminous or petroliferous rocks throughout the valley. From that date onward no further geological study of the region was made until the investigation by Dr. Bosworth, in 1914. It was not until 1919 that a drilling outfit was conveyed into the North-West Territory, the oil claims having been acquired by the Imperial Oil Company, who were conducting an exhaustive search for oil throughout Canada. The location of this first test well was chosen in 1914, as a site where a hole of moderate depth could not fail to penetrate the several petroliferous formations which had been found. The well is on the river bank about half-way down the Long Reach, near the mouth of Camp Creek, where there are copious seepages of oil. Geologically speaking, the location is upon the outcrop of the lower measures of the Camp Creek Series, low down on the south-west flank of the Wolverine Anticline, about eight miles from the axis of the fold. It was clear that the oil rocks would lie rather shallow here, but by refraining from going further down the dip there was less risk of finding the beds occupied by water, and also there was less chance of failure to reach the desired horizons occasioned by engineering difficulties in such a remote country. The well was drilled during the summer of 1920. Almost from the start oil was coming into the hole; and before a depth of 100 ft. was reached, a yield of five or ten barrels a day could be obtained. After passing from the Camp Creek Series into the dark Fort Creek shales, the oil showings still continued, until at a depth of 783 ft. a strong flow of oil was encountered which spouted to a height of 70 ft. After about ten minutes the well was capped. Some hundreds of barrels of oil issued from the well before it was finally shut in, but no dependable estimate of its capacity can yet be made. It is thought that the initial output will be at least 500 barrels a day. Whether or not this first well will settle down as a steady, large producer yet remains to be seen. And, in any case, many more wells must be drilled before the importance of the field is fully proved.

Dr. Bosworth proceeded to give an outline of the geology of the region. The strata exposed in the Mackenzie oilfield district include:

Tertiary ...	Shales, sandstones, and lignites.
Cretaceous ...	Clay-shales and sandstones.
Devonian ...	Limestones, shales, and sandstones.
Silurian	Limestones, etc.

It is in the Devonian only that the oil and gas have been found. In the region containing the lower part of the Mackenzie River, from Fort Norman northward, the Devonian is divided provisionally by Dr. Bosworth into the following main groups:

		Thickness in ft.
Camp Creek Series.	Clay-shales and sandstones. Greenish and variegated. Marine shells and plant particles.	2,000+
Fort Creek Series.	Bituminous shales with thin seams of sandy limestone. Black, but in places burnt brick-red. Plants and marine shells.	500–1,000
Beavertail	Bituminous limestone beds. Black or dark. [illegible] and other marine fossils	350
Rampart Limestone.	Massive grey limestone. Many fossils, marine.	100–200
Hare River Shales.	Calcareous clay-shale. Grey-green. Few fossils, marine.	300
Barren Series	Brecciated dolomite and white, grey, and buff limestones, without fossils.	2,000 (?)

After passing Fort Norman, the river comes in contact with a mountain system, referred to as the Limestone Mountains. These mountains, which consist of anticlinal folds of Devonian rocks, are encountered by the river for a distance of a hundred miles. It is in this territory that the favourable indications and structural conditions were found, which have led to the recent strike of oil. This is the site of the new oilfield. A few miles beyond Fort Norman, the Mackenzie turns sharply to north-westward, so as to flow along the S.W. flank of the Limestone Mountain range. This straight course, known as the Long Reach, is maintained for 75 miles, parallel with the range, and a few miles from it. The river then turns northward, and in a distance of 25 miles it cuts across the trend of the mountains, at their western end. The Devonian strata of the Limestone Mountain district have been thrown into a series of bold asymmetrical folds, whose axes plunge up and down, steeply and frequently. In the synclines, the soft Camp Creek

series and Fort Creek shales give rise to low ground. But wherever the upward pitchings of the anticlinal axes bring the arches of the Beavertail limestone up above the general level of the land, the denudation has developed out the arches, as conspicuous anticlinal hills. Four main anticlines are thus revealed where the Mackenzie River crosses the folds. At this place all of them are pitching down toward the west. In order from south to north, they have been named by the author: Wolverine, East Mountain, Bat Hills, and Beavertail. Anticlinal structure in the region was first observed at Bear Mountain by R. G. McConnel, but the main folds were found and mapped by the author in 1914. The four axes lie roughly parallel, at intervals of about seven miles. Their direction, where the river crosses them, is slightly north of east; but on the east side of the river they bend round to a E.S.E. course, which is perhaps their more important direction. These four main anticlines are very much alike, each forming a line of more or less discontinuous limestone hills, exceeding 1,000 ft. in height. In each of these anticlinal ranges a core of the grey barren limestones, or the Fort Norman limestones, is laid bare in the parts where the axis rises to its maximum height. On each of them the bituminous Beavertail limestone forms steep dip-slopes; and generally it is also seen forming conspicuous arches on some parts of the crests. Low down on the flanks, the Fort Creek shales are found, followed by the soft Camp Creek beds. Near the axes, the strata at the core are very steeply inclined; but a mile or two away, on the flanks of the anticlines, the dip is 15° to 35°.

It was the remarkable character of the Fort Creek Shales and Beavertail Limestone, rather than the oil seepages, which led to a favourable view of the prospects in this field. For here, extending over a large region, there are 1,000 to 1,500 ft. of highly bituminous rocks, which obviously are a potential source for the generation of a great quantity of petroleum. These limestones and shales are black with bituminous material, which appears to be present, not as a migratory, but as a fixed constituent. In some places where these beds are much exposed, the bituminous odour is so strong that it may be noticed at a distance of half a mile. The bituminous shales are undergoing slow combustion at their outcrop, and often they are burnt to a bright brick-red colour, or even to a grey colour, becoming so hard that they clink when struck. In several localities there are conspicuous cliffs of these bright red rocks, over a hundred feet high. Fluid oil is not visible in the bituminous rocks, though where they pass under water some liberation of gas is seen. But oil might reasonably be expected in the porous beds of the overlying thick series of clay shales and sandstones, and also there was a good chance that at depth, and under favourable structure, accumulations of petroleum might occur within the black shales and limestones themselves. After study of the bituminous beds, the sands of the overlying Camp Creek Series were searched for oil. At each place examined, either seepages were found, or the presence of oil was detected on crushing the rock under water. The principal seepages occur on the shores of the Long Reach, where the river flows for seventy-five miles along the outcrop of the Camp Creek Series. Near the mouth of Camp Creek (which at first was called Oil Creek) the seepages are conspicuous for a distance of two and a half miles. On digging in the river gravel, the outcrops of the green oil-sands are exposed, and the oil could be collected in considerable amount. Further out in the river much oil rises up to the surface of the water, and in winter it collects, forming pools on the ice.

The oil has a paraffin base and is of high quality. The seepage oil, obtained on digging in the outcrop of the Camp Creek beds, has a greenish black colour, and a strong paraffin smell. The specific gravity is 0·905. The crude oil from the well is of light colour, low specific gravity, high gasoline content, and low cold test.

Dr. Bosworth's paper contains also a large amount of information as to the general stratigraphy, means of access and transport, the structure of the individual anticlines, and analyses of the oil.

Andean Geology.—At the meeting of the Geological Society of London held on April 29, J. A. Douglas read a paper entitled: "Geological Sections through the Andes of Peru and Bolivia, III, from Callao to the River Perene." This paper is the third of a series by the writer dealing with the geological structure of the Andes of Peru. The ancient rocks of the coastal Cordillera of the south are no longer met with in Central Peru, and the zone of Mesozoic rocks extends to the Pacific coast, which is here formed of shallow-water deposits of Lower Cretaceous age. The granodioritic batholith which forms the core of the Andes is encountered in the neighbourhood of Lima, and again almost at the summit of the range. The western flanks of the Cordillera are characterized by a great development of Cretaceous porphyritic agglomerate; while the normal calcareous facies is the dominant feature of the high-level regions. The intensity of the Tertiary folding has obscured the effects of the post-Jurassic uplift, previously shown to occur in the south, and it is only on palæontological evidence that a break in the sequence of Mesozoic deposits can be determined. Intrusions of andesite and dacite in the form of volcanic necks are of common occurrence; but there is no trace of recent volcanic activity in this area. The fossiliferous Devonian and Permo-Carboniferous deposits of the Titicaca district are not continued into the region here described. The rocks of Palæozoic aspect which form the eastern flanks of the Cordillera are, for the greater part, unfossiliferous, and have largely been converted into phyllites and mica-schists, penetrated by granite, which has also shared in the metamorphism. On the Rio Perene another and much bigger mass of red granite is met with. This is essentially a rock of alkaline character, as distinct from the calcite granodiorites of the Cordillera. It is suggested that its origin, like that of a similar rock in the coastal Cordillera of the south, dates from a very early period, antecedent to the uplift of the mountain-ranges.

In the discussion following the reading of the paper, Dr. J. W. Evans said that the comparison between the geology of this section across the Andes with those previously described was full of interest. He suggested that the change of strike from roughly north-west towards north-north-west was not without significance. Ultimately, still farther north, the strike became north and south. In a paper on the rocks of the Madeira Falls he, the speaker, had contended that the lines of folding in South America with a north-west and south east direction were older than those striking north and south, and this view was consistent with the facts adduced by the author of the paper just read.

Professor W. J. Sollas said the author had wisely abstained from entering upon hypothesis, but it would be interesting if he could inform them as to what he thought about the mechanism of mountain-building. In such a lofty range one might well have expected mighty overthrusts, some plains of Piedmont overriding the high Alps, but they were told of nothing worse than strata vertically upreared on end and some overfolds. The igneous intrusions were, however, on a grand scale, and it looked as though it might be necessary to make a partial return to hypotheses now out of date. Possibly

batholiths may have played a more important part than the opinions at present fashionable would concede.

The author, in reply to the discussion, said he fully agreed with Dr. Evans that much of the evidence tended to show that the folding was not contemporaneous throughout the length of the chain. In the Jurassic rocks, for example, deposition appeared to have ceased with the Lower Lias in the district now described; farther south it was continued into Bajocian times, while in the north of Chile beds of Oxfordian age were found. The transition of the fossiliferous, Cretaceous limestones of the north into the gypsiferous red sandstones of the south was also a significant feature. In reply to Professor Sollas, he said that the facts now recorded were in no way opposed to the views that he had previously expressed as to the nature of the processes which gave rise to the uplift of the Andes. The great granite mass of the Perene formed, with the nepheline-syenites of the Inambari district, one of the jaws of the vice that had compressed the transgressive deposits of the geosyncline. Fragments of the other jaw were to be found in the similar granite of the coastal Cordillera

SHORT NOTICES.

Drilling for Oil.—At the meeting of the Institution of Petroleum Technologists held on April 19, Alan W. Davson read a paper on the education and training of a driller.

Mine Atmospheres.—The March *Journal* of the South African Institution of Engineers contains a paper by A. J. Orenstein and H. J. Ireland on the effect of heat and moisture on workers in mines.

Roof Supports in Mines.—The *Iron & Coal Trades Review* for April 1 publishes an illustrated paper by Alfred Terrell on the best methods of supporting the roof and sides of roadways and working places in coal mines.

Ventilating Currents.—At the April meeting of the Mining Institute of Scotland, David Penman described a new method of measuring ventilating resistances, with special reference to the operation of mine fans in combination.

Shaft-Sinking.—At the April meeting of the Manchester Geological and Mining Society, Charles Walker read a paper describing his system of sinking shafts through wet ground, being a modification of the cementation process.

Mining Costs.—At the March meeting of the Institution of Mining and Metallurgy, A. E. Pettit presented a paper on "Notes and Records of Mining Costs."

Gunite.—In the *Engineering and Mining Journal* for March 26, G. J. Young writes on the application underground of gunite, that is to say, cement mixture put in place by an air-blast machine.

Cyaniding in Ecuador.—In the *Engineering and Mining Journal* for April 2, P. C. Schraps describes the cyanide plant at the Zaruma gold mine, Ecuador.

Electrolytic Zinc.—At the April meeting of the Faraday Society, Samuel Field read a paper on electrolytic zinc, recounting the work done by him at Swansea. We gave a notice of a previous paper by him in the issue of October last. Comment is made on this subject in *Engineering* for April 1.

Nickel-Copper Alloys.—In *Chemical and Metallurgical Engineering* for March 30, P. D. Merica discusses alloys of nickel and copper, particularly in connection with coinage alloys

Copper in Steel.—In *Chemical and Metallurgical Engineering* for March 30, E. A. and L. T. Richardson continue the discussion of the influence of copper on the physical properties of iron and steel.

Colorado Oil-Shales.—In *Chemical and Metallurgical Engineering* for March 30, A. J. Franks discusses distillation problems in connection with Colorado oil-shales.

Potash Alum and Sulphur In *Chemical and Metallurgical Engineering* for March 23, L. Duncan describes the recovery of potash alum and sulphur, occurring in rhyolitic tuffs at Tonopah, Nevada.

Feld's Ammonium Sulphate Process.—The *Chemical Trade Journal* for April 16 contains notes on the Feld direct process for producing ammonium sulphate at gas works. Reference to this process was made in the MAGAZINE for August, 1912.

Haber Ammonia Process.—In the *Journal* of the Society of Chemical Industry for March 31, J. R. Partington describes the operation of the Haber synthetic ammonia process as operated by the Badische Anilin & Soda Fabrik at Oppau.

Jarosite in Victoria.—*Chemical Engineering and Mining Review* (Melbourne) describes a deposit of jarosite, the basic sulphate of aluminium and potassium, near Anglesea, Victoria.

Gold in Victoria.—*Economic Geology* for March contains an article by N. R. Junner on the geology of the gold occurrences in Victoria

Oil Geology.—In *Economic Geology* for March, R. A. Mills discusses the relation of texture and bedding to the movements of oil and water through sands.

Phosphates in Pacific Islands.—The *Journal* of the Society of Chemical Industry for March 31 contains a report of a paper read by T. Steel before the Sydney section on the phosphate deposits of Nauru and Ocean Islands, in the Pacific Ocean.

The Pas, Manitoba.—The *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper on the occurrence of gold at Herb Lake, The Pas district, Manitoba.

Peat Power in Germany.—The *Engineer* for April 22 describes the scheme for supplying electric power throughout Germany from seven generating stations where steam power is obtained by the combustion of peat

Conditions in Silesia.—In the *Colliery Guardian* for April 1, Edgar P. Rathbone gives his experiences during a recent visit to Upper Silesia.

RECENT PATENTS PUBLISHED.

☞ *A Copy of the specification of any of the patents mentioned in this column can be obtained by sending 1s to the Patent Office, Southampton Buildings, Chancery Lane, London, W C 2, with a note of the number and year of the patent*

14,794 of 1920 (144,276). W. TYRRELL, Seattle, U.S.A. Binder for briquetting ores consisting of diatomaceous earth, sulphate of soda, concentrated lye, and magnesium carbonate.

15,878 of 1920 (144,725). J. E. KENNEDY, New York. Combined ball and tube mill.

19,013 of 1920 (160,708). F. MILLIKEN, New York. An alloy consisting of copper, nickel, zinc, and iron, capable of resisting acids at high temperatures.

20,763 of 1919 (159,525). C. J GRACE, Truro. Machine for drying china-clay or other plastic material.

21,812 of 1919 (160,477). R. L. LLOYD, New York. Improvements in the Dwight-Lloyd sintering plant.

24,721 of 1919 (159,530). BRITISH OXYGEN CO., London. Improved furnace for reducing metals from oxides by the action of hydrogen.

26,136 of 1919 (159,537). ARMSTRONG, WHITWORTH & CO., Newcastle-on-Tyne. An alloy which is non-corrosive and has a high resistance to the action of steam, consisting of 82½% copper, 9½% aluminium, 5% manganese, and 3% iron.

27,561 of 1919 (135,179). A. KNOBLOCH and O. MANDL, Teplitz, Czecho-Slovakia. Boring machine for driving tunnels and levels.

28,228 of 1919 (159,942). H. J. THACKERAY, Chesterfield. Combined metal and wood pit-prop.

29,216 of 1919 (159,568). W. B. BALLANTINE, London. Making a pure ferro-chrome by removing carbon from crude ferro chrome by means of an oxidizing blast, and then adding a thermo-reduction mixture containing a chromium compound so as to adjust the desired chromium content.

29,293 of 1919 (137,513) and **29,539 of 1919 (149,927).** NEW JERSEY ZINC CO., New York. Improvement in the method of producing zinc oxide by the Wetherill intermittent process.

29,965 of 1919 (159,950). TRAYLOR ENGINEERING & MANUFACTURING CO., Allentown, Pennsylvania. Improved construction of gyratory crushers.

30,816 of 1919 (160,231). F. S. NEWALL, Newcastle-on-Tyne. Improved electric furnace for calcining magnesite.

30,884 of 1919 (159,659). J. R. BROADLEY, J. M. LEE, and L. STEVENS BURT, London. Centrifugal pump, illustrated as the Wilfley pump in the MAGAZINE for February.

30,950 of 1919 (159,659). J. J. COLLINS, Winsford, Cheshire. Purification of tin and the production of tin salts from crude tin.

31,359 of 1919 (160,254). J. M. and A. T. HOLMAN, Camborne. Machine for sharpening rock-drill steels.

32,132 of 1919 (160,554). S. O. COWPER-COLES, London. Method of stripping electrically deposited sheets of metal.

32,243 of 1919 (133,459). J. DELECOURT, St. Ghislain, Belgium. Improved method of drilling by percussion.

32,416 of 1919 (160,293). J. L. MENNELL and CHAS. BUTTERS & CO., LTD., London. Apparatus for giving a continuous indication of the density of a liquid as it flows through a tank and for delivering the liquid as it leaves the tank to one of a number of launders according to its density.

2,077 of 1920 (159,737). OSMOSIS CO., W. R. ORMANDY, and D. NORTHALL-LAURIE, London. Method of vitrifying china-clay deposited by osmosis.

4,976 of 1920 (139,195). V. GERBER, Zurich. Method of producing aluminium nitride.

10,756 of 1920 (160,373). GENERAL ELECTRIC CO., Schenectady, New York. Method of making filament for electric lamps containing 95% tungsten and 5% silicon.

17,388 of 1920 (145,709). FRIED. KRUPP, Essen, Germany. Making low-carbon ferro-chrome by blowing high-carbon ferro-chrome in a converter.

18,079 of 1920 (160,395). E. W. DAHL, London. Plant for manufacture of white lead.

19,202 of 1920 (160,114). T. H. OSWALD and A. D. D. BROWN, London. Plant for distilling oil from sandstone, shale, etc.

19,675 of 1920 (147,689). R. E. BEA, Paris. Electrolytic vat for producing sulphate of copper from copper waste and scrap.

20,078 of 1920 (148,168). H. SCHRANZ, Freiberg, Germany. Making concentrating surfaces of porous material through which air or water may pass upward.

26,523 of 1920 (156,472). J. RHEINBERG, London. Improved method of producing metallic surfaces on glass, consisting of platinum or metals of the platinum group, intended for use as mirrors.

NEW BOOKS, PAMPHLETS, Etc.

☛ Copies of the books, etc., mentioned below can be obtained through the Technical Bookshop of *The Mining Magazine*, 724, Salisbury House, London Wall, E.C.2.

Well-Boring for Water, Brine, and Oil. By C. ISLER. New Edition. Cloth, octavo, 212 pages, illustrated. Price 16s. net. London: E. & F. N. Spon, Ltd.

Storage of Petroleum Spirit and Calcium Carbide. By Major A. COOPER-KEY. Cloth, small octavo, 135 pages. Price 5s. net. London: Charles Griffin & Co., Ld.

Recent Practice in the Use of Self-contained Breathing Apparatus. By REX C. SMART. Cloth, octavo, 250 pages, illustrated. Price 15s. net. London: Charles Griffin & Co., Ltd.

Elementary Text-Book on Mechanical Drawing. By JOHN E. JAGGER. Cloth, quarto, 250 pages, illustrated. Price 15s. net. London: Charles Griffin & Co., Ltd.

Catalogue of the Collections in the Science Museum, South Kensington. Price 1s. net. This section of the catalogue describes the exhibits relating to mining and ore-dressing.

Geology of the British Empire. By F. R. C. REED. Cloth, octavo, 480 pages, illustrated. Price 40s. net. London: Edward Arnold.

West Australian Geological Survey, Bulletin 83. Geology and mineral resources of the north-west, central, and eastern divisions. By H. W. B. TALBOT and R. A. FARQUHARSON.

Aluminium and Bauxite. Published by the Imperial Mineral Resources Bureau. Price 9s. net.

Bismuth 1913 to 1919. Pamphlet published by the Imperial Mineral Resources Bureau. Price 6d

Thorium, Zirconium, and Rare-Earth Minerals, 1919. By W. T. SCHALLER. Published by the United States Geological Survey.

COMPANY REPORTS

Tharsis Sulphur & Copper.—This company has worked pyrites mines in the south of Spain since 1866. The headquarters are in Glasgow, and it has several works in this country where burnt pyrites is treated for the recovery of copper. The report for 1920 shows that 251,620 tons of ore was raised from the Calanas mine, and 62,298 tons from the Tharsis, making a total of 313,918 tons, as compared with 260,801 tons in 1919. The new Sierra Bullones open-cut at Tharsis is now yielding a steady supply of ore, and the North Lode will shortly be drawn upon for shipping ore. The metal works have been fully employed during the year, and the amount of material treated has been exceeded only twice in the history of the company. The net profit was £134,949, out of which £131,250 has been distributed as dividend, being at the rate of 15%. The total dividends since the beginning have been £10,999,057, and £2,729,109 has been written off property and plant account.

Mason & Barry.—This company has worked the San Domingos cupriferous pyrites mines at Mertola, Portugal, since 1853, and has made large profits. During the war the restriction of trade and shipping facilities seriously interfered with the business of the company. The report for 1920 shows that conditions have improved again. The amount of ore raised was 93,812 tons, as against 60,522 tons in 1919. The shipments, inclusive of washed pyrites, amounted to 226,739 tons, as against 41,827 tons in 1919. The profit was £67,685, out of which £46,293 was paid as dividend, being at the rate of 25%. The sum of £5,000 was placed to the

account of the staff pension fund.

Sons of Gwalia.—This company was formed in 1898 to work a gold mine near Mount Leonora, West Australia. Bewick, Moreing & Co. are the managers. The report for 1920 shows that 135,230 tons of ore was treated for a yield of 41,690 oz., realizing £255,234, of which £77,353 represented premium. The working profit was £60,257, from which has to be deducted £16,310 for taxes and £8,288 for depreciation. The dividend absorbed £16,250, being at the rate of 5%. As already reported, a fire destroyed most of the mill and treatment plant in January, and the stoppage of productive operations followed. The directors intend to rebuild the plant, and have placed £20,000 out of the year's profit to the account for continuing development and providing new plant. Satisfactory settlement has been made with the insurance companies.

Ooregum Gold.—This company belongs to the John Taylor group, and operates a gold mine in the Kolar district, Mysore State, South India. The report for 1920 shows that 153,350 tons of ore was treated, yielding 96,268 oz. of gold. The amount of ore treated was about the same as the year before, but the yield of gold was 5,834 oz. greater. This rise is accounted for by the policy adopted of working richer ore so as to provide funds for sinking the new shaft and for supplying new plant necessary for continuing work at depth. The gold realized £499,756, and the working profit was £226,017. The shareholders received £93,173, the dividend rates being 32½% on the preference shares and 22½% on the ordinary shares. There was written off for depreciation £18,000, and £33,182 for expenditure on the new circular shaft; while £50,000 has been allocated to mine equipment account. The ore reserve is estimated at 422,656 tons, a fall of 5,310 tons on the year. In the lowest levels of the mine, namely, the 61st and 62nd in Oakley's section, and the 59th to 62nd levels in Bullen's section, the lengths of ore are not so great as in the levels above, owing to intrusions of pegmatite, but the ore is of good quality.

Gopeng Consolidated.—This company was formed in 1912 as a consolidation of the Gopeng and New Gopeng, which had been operating alluvial tin properties in Perak, Federated Malay States, since 1892 and 1903 respectively. The object of the consolidation was to facilitate the financing of a scheme, undertaken conjointly with Kinta Tin Mines, Ltd., for bringing a new supply of water at higher pressure for use in hydraulicking from the Kampar river. The control of the company is in Redruth. James Wickett is chairman, and Osborne & Chappel are the engineers. The report for the year ended September 30 last shows that, owing to an unusual drought, less tin ground could be treated, the figure being 1,115,196 cu. yd., as compared with 1,423,283 cu. yd. during the previous year. The output of tin concentrate was 733½ tons, as compared with 836 tons the year before, and the yield per yard was 1·48 lb. as compared with 1·32 lb. The income from the sale of concentrate was £133,745, and the working cost was £43,736. Dividends and interest brought an income of £5,931. The total profit was £97,399, out of which £59,365 was distributed as dividend, being at the rate of 15 per cent.

Tekka-Taiping.—This company was formed in 1913 as a subsidiary of the Tekka for the purpose of acquiring an alluvial tin property at Taiping in the Larut district of Perak, Federated Malay States. James Wickett is chairman, and Osborne & Chappel are the engineers. Operations were started with a pump-dredge, but a bucket-dredge was substituted later. A second bucket-dredge is on order. The report for the year ended October 31 last shows that 892,020 cu. yd. of ground was treated, for a yield of 394·9 tons of tin concentrate, being at the rate of 0·99 lb. per yard. The income was £70,023, and the working profit was £43,802, out of which £17,433 was paid as dividend, being at the rate of 5%. The allowance for depreciation of plant was £5,000, and a large balance was kept in hand pending settlement of liability for taxation. The yield from the ground treated was much higher than the calculated contents, the bore-hole figures calling for only 0·63 lb. per yard.

Rambutan.—This company belongs to the Wickett group, of Redruth, and was formed in 1905 to work alluvial tin ground in the northern part of the Kinta district, Perak, Federated Malay States. A pump-dredge was used at first, but hydraulic elevating was adopted afterwards. The report for the year ended June 30, 1920, shows that 212 tons of tin concentrate was extracted from 504,752 cu. yd. of ground, being a yield of 0·95 lb. per yard. The income from the sale of concentrate was £40,355, and the working profit was £25,403, out of which £15,000 was distributed as dividend, being at the rate of 15 per cent.

Pengkalen.—This company belongs to the Wickett group, of Redruth, and was formed in 1907 to work alluvial tin ground at Lahat, in the state of Perak, Federated Malay States. At first an electrically-driven pump-dredge was installed, but it did not give good results. A bucket-dredge is on order, and in the meantime the property has been let on tribute. A substantial income is at present realized by the sale of electric power to other mining companies, and this electric plant is being extended. The report for the year ended September 30 last shows that the income from tribute was £6,473, and from the sale of power £27,926, while £1,450 was received as dividends from investments. The costs at the mine and power plant were £19,789, and the working profit was £15,412, out of which £5,000 was written off for depreciation of plant, while £7,088 was distributed as dividend, being 15% on the preference shares and 5% on the ordinary shares.

Chendai Consolidated.—This company belongs to the Wickett group, of Redruth, and was formed in 1914 as a consolidation of the Redhills, Sungei Chendai, and the Chendai Lodes companies, operating in the Kinta district of Perak, Federated Malay States. The report for the year ended April 30, 1920, shows that the lode property was not worked owing to deficiency of available ore, and that the ore in the bottom level could not be mined owing to water in the stopes. A small amount of development work was done. The alluvial properties were let to tributers, who won 37 tons of tin concentrate, selling for £5,782, of which £780 accrued to the company as tribute. The company's accounts for the year show a loss of £823.

Plymouth Consolidated Gold Mines.—This company was formed in 1914 by Bewick, Moreing & Co. to acquire a gold mine, reported on by W. J. Loring, in Amador County, California. Dividends were paid regularly from 1915 to 1919. The report for 1920 shows that owing to unavoidable curtailment of development during preceding years, the tonnage of ore treated showed a decrease, being 91,350 tons as compared with 119,200 tons during 1919. The yield of gold was £121,799 as compared with £148,666; and the yield per ton 26s. 8d. as compared with 24s. 11d. per ton. As the mine is in the United States, no premium is received on the sale of gold. The working cost was £110,614, and after allowance for depreciation and American taxes, the total cost was £122,382, leaving a balance of profit of £2,358. The working cost per ton was 24s. 2d., as compared with 18s. 9d. in 1919, and 16s. in 1918. The advance in cost was due to increased wages and

prices of materials. The development done during the year has given satisfactory results. The No. 2 South ore-shoot was developed at the 1,500 and 1,600 ft. levels where, although the shoot was narrow, high values were disclosed, and the main and north foot-wall ore-shoots were opened up with good results at the 2,600 and 2,750 ft. levels respectively. At the 2,900 ft. level high-grade ore was developed, which it is believed forms the apex of a new shoot subsequently opened up at the 3,050 ft. level where, for a length of 204 ft., it averaged 57s. per ton over a width of 80 in. A winze from the latter level was sunk 50 ft. in ore averaging 54s. 6d. per ton over an exposed width of 92 in. The shoot was also intersected by a cross-cut from the shaft at the 3,120 ft. level, and averaged 33s. 6d. per ton over a width of 108 in. To expedite the opening up of this new ore-body the winze mentioned is being continued concurrently with shaft-sinking, and it is expected that when work has advanced sufficiently to enable the concentration of mining operations on this section, an improvement will result, not only in the output, but also in working costs.

Santa Gertrudis.—The report of this company, which works silver mines at Pachuca, Mexico, shows that during the year ended June 30, 1920, 356,753 tons of ore from the Santa Gertrudis and 120,322 tons from the El Bordo group were treated, for an extraction of 4,430,433 oz. of silver and 23,070 oz. of gold. The net profit was £237,384, of which £65,000 was allocated to income tax, while £150,000 was distributed as dividend, being at the rate of 10%. Developments at the Santa Gertrudis mine continue to give little result, and the reserve is estimated at 476,678 tons with recoverable contents of 4,309,556 oz. of silver and 24,382 oz of gold. At the El Bordo group, developments at the El Bordo property have given good results and the reserve has been substantially increased, standing now at 1,064,180 tons, the recoverable content being estimated at 11,000,000 oz. of silver and 48,400 oz. gold. At the Malinche mine development has been continued, but more work will have to be done before the value of the deposit can be ascertained. The reserve is estimated at 102,810 tons, containing 832,190 oz. silver and 3,670 oz. gold recoverable. Transport connection has been made with the El Christo mine, and shipments have commenced. The reserve is estimated at 147,750 tons, containing 1,188,300 oz. silver and 5,225 oz. gold recoverable. The company owns 250,000 £1 shares and £70,000 seven-year notes in the Mexican Corporation; also 49,996 £1 shares in the Mexican Chemical & Metallurgical Corporation, which was formed in January, 1920.

Camp Bird.—The report of this company for the year ended June 30, 1920, shows that the exploration conducted upward by means of the long tunnel has been continued, but that no important runs of gold ore have been discovered. The company received £58,917 as dividend on its holding in Santa Gertrudis, and made a profit of £50,320 by realization of certain investments. The accounts show a profit of £29,451. Dividends on the preference shares declared for the year absorbed £45,473. The company has subscribed for 100,000 £1 shares in the National Mining Corporation, and for 250,000 £1 shares and £70,000 seven-year notes in the Mexican Corporation; also for 24,998 £1 shares in the American Chemical & Metallurgical Corporation, which was registered in January, 1920.

Mexican Corporation.—This company belongs to the Camp Bird group, and was formed in July, 1919, to work the Fresnillo silver mine in Zacatecas, and the Teziutlan copper mine in Puebla. The company's interest in these mines is that it is supplying money for reorganizing and extending the scale of operations in return for 40% and 37½% respectively of the net profits. The company has also invested funds in the National Mining Corporation, and the Burma Corporation; it has a share in the Union en Cuale option obtained by the Esperanza company; and it holds an interest in the British Equatorial Oil Company. The report now issued covers the period from the formation of the company to the end of June, 1920. It is here stated that £999,396 had been dispatched to Mexico for capital purposes by December 31, 1920. Particulars are also given of the development work. At the Fresnillo mine there are two separate workings, one in an oxidized surface ore-body, and the other a system of deeper workings containing complex sulphide ore. The surface ore-body is estimated to contain 4,000,000 tons of ore which is easily treated by cyanide. The sulphide ore will probably have to be submitted to some concentration process before treatment. During the period November 1, 1919, to June 30, 1920, there was treated 100,901 tons from the surface ore-body, from which 390,744 oz. silver and 531 oz. gold were extracted. Also 96,225 tons of old tailing was treated, yielding 180,141 oz. silver and 428 oz. gold. At the Teziutlan property concentration plant has been erected, having for its chief object the removal of the zinc from the copper ore. During the period above-named, 35,256 tons of ore and concentrate was smelted, and the blister copper produced contained 2,199,692 lb. copper, 829 oz. gold, and 58,451 oz. silver.

Randfontein Central.—This company owns property in the farthest west Rand. The control passed a few years ago from J. B. Robinson to the Barnato group, under whose auspices the underground work was entirely reorganized. The report for 1920 shows that 1,561,330 tons of ore, averaging 5·62 dwt. per ton, was raised and sent direct to the mill. The yield of gold by amalgamation was 240,099 oz., and by cyanide 170,714 oz., making a total of 410,813 oz., equal to 5·26 dwt. per ton. The revenue from the sale of gold was £2,300,695, of which about £550,000 came from premium. The working cost was £2,142,595, leaving a working profit of £158,100. Against this profit was charged £138,580 for debenture interest, and £34,769 for interest on the loan advanced by the controlling house. The revenue per ton was 29s 5d., and the working cost 27s. 5d. The ore reserve is estimated at 3,593,410 tons, averaging 6·2 dwt. per ton. Of the two new main vertical shafts, the northern is already in commission, and the southern will be ready in July or August. The new development work has disclosed ore, in addition to the proved reserves, which is likely to last for many years.

Durban Roodepoort Deep.—This company belongs to the Central Mining-Rand Mines group, and was formed to work a deep-level property in the middle west Rand in 1895. The report for 1920 shows that 308,713 tons was raised, and after the rejection of 10% waste, 277,200 tons was sent to the mill. The yield of gold by amalgamation was 62,337 oz., and by cyanide 26,533 oz., making a total of 88,870 oz., or 6·4 dwt. per ton. The revenue from the sale of gold was £490,620, of which £112,900 represented premium. The working cost was £476,937, leaving a working profit of £13,682. The revenue per ton was 35s. 5d., and the working cost 34s. 5d. The development during the year was restricted owing to the shortage of labour, but the results obtained were good, 196,200 tons averaging 7·1 dwt. per ton being proved. The reserve is estimated at 1,094,900 tons averaging 6·6 dwt. per ton. During the first half of the year, when the gold premium was low, operations were being carried on at a loss, and the directors deemed it advisable to stop the sinking of the new vertical shaft, which had reached a depth of 2,272 ft. This shaft is necessary if working costs are

to be reduced, and the directors are now considering the advisability of resuming sinking.

Langlaagte Estates & Gold.—This company belongs to the Barnato group and works an outcrop property in the western portion of the central Rand. The report for 1920 shows that 465,300 tons averaging 6·2 dwt. per ton was mined and sent direct to the mill. The yield of gold by amalgamation was 83,181 oz., and by cyanide 55,592 oz., being a total of 138,773 oz., or 5·96 dwt. per ton. The revenue from the sale of gold was £774,031, of which £184,000 represented premium, and the working profit was £153,352. The revenue per ton was 33s. 3d. and the working profit 6s. 7d. The shareholders received £88,650, the dividends (Nos. 59 and 60) totalling 10%. Development has continued to give satisfactory results. The ore reserve is estimated at 1,016,800 tons averaging 6·4 dwt. per ton.

Consolidated Langlaagte Mines.—This company belongs to the Barnato group, and operates a deep-level mine in the western part of the central Rand. The report for 1920 shows that 484,247 tons of ore was raised and sent direct to the mill, together with 19,653 tons taken from the dumps. The average assay-value of the ore treated was 6·1 dwt. per ton. The yield of gold by amalgamation was 104,716 oz., and by cyanide 39,853 oz., making a total of 144,569 oz., or 5·74 dwt. per ton. The revenue from the sale of gold was £806,076, of which about £190,000 represented premium. The working profit was £185,109. The revenue per ton was 31s. 11d., and the working profit 7s. 4d. The shareholders received £118,750, the dividends (Nos. 13 and 14) being together 12½%. Developments in the bottom levels were very discouraging. The ore reserve is estimated at 1,339,000 tons, averaging 6·2 dwt., as compared with 2,090,300 tons of the same tenour last year. The fall in the reserve is due not only to poor developments, but also to some of the ore in the Leader proving of lower grade than originally estimated.

Village Deep.—This company belongs to the Central Mining-Rand Mines group and works a deep-level property in the central Rand to the west of City Deep. The report for 1920 shows that 604,686 tons of ore was raised, and after the removal of 8% waste, 555,800 tons averaging 6·63 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 113,039 oz., and by cyanide 60,187 oz., making a total of 173,226 oz., or 6·23 dwt. per ton. The gold was sold for £956,921, of which about £220,000 represented premium. The working cost was £828,339, leaving a working profit of £128,581. The revenue per ton was 34s. 5d., the cost 29s. 10d., and the profit 4s. 7d. The shareholders received £106,067, the dividends being at the rate of 10%. The development during the year gave fairly good results, and 533,700 tons averaging 6·3 dwt. per ton was proved. The reserve is estimated at 2,381,200 tons averaging 6·1 dwt. per ton; of this amount, 508,900 tons averaging 5·9 dwt. is in pillars. The main incline shaft has been sunk to the 32nd level, and is now 6,059 ft vertically below the outcrop.

City Deep.—This company belongs to the Central Mining-Rand Mines group, and works a deep-level property in the central Rand. The report for the year 1920 shows that following on the absorption of the City & Suburban it was possible to increase the native labour supply. Consequently a much larger amount of ore was milled. In fact, for the first time in the history of the mine, it was possible to work the mill at full capacity. The amount milled was 862,500 tons, compared with 617,800 tons in 1919 and 670,000 tons in 1918. The assay-value of the ore milled was 8·45 dwt. per ton. The yield of gold by amalgamation was 252,828 oz., and by cyanide 98,533 oz., making a total of 351,361 oz., or 8·14 dwt. per ton milled. The income from the sale of gold was £1,951,330, of which about £458,000 was due to premium, the average price obtained for the gold being 111s. per oz. The revenue per ton was 45s. 3d. The working cost was £1,301,981, or 30s. 2d. per ton, leaving a working profit of £649,348, or 15s. 1d. per ton. Dividends absorbing £415,250 were distributed, being at the rate of 32½%. The profit was £191,661 higher than that for 1919. The cost per ton has continued to increase, and compares with 27s. 9d. in 1919 and 24s. 8d. in 1918. The developments have not been quite as good as they were during the previous few years; nevertheless 598,500 tons averaging 8·9 dwt. was proved. The reserve is estimated at 3,099,200 tons averaging 9 dwt. per ton, as compared with 3,418,452 tons averaging 9·4 tons the year before. The sinking of the new shaft near the southern boundary, which will be 7,000 ft. deep, has been described in a paper by E. H. Clifford, quoted in our March issue.

Crown Mines.—This company belongs to the Central Mining-Rand Mines group, and works deep-level ground in the central Rand. The report for 1920 shows that 2,254,583 tons of ore was raised, of which 1,342,676 tons came from the Main Reef Leader, 949,731 tons from the South Reef, and 150,965 tons from the Main Reef. After the removal of 10% waste, 2,201,000 tons, averaging 6·35 dwt. per ton, was sent to the mill. The yield of gold by amalgamation was 496,589 oz., and by cyanide 175,016 oz., making a total of 671,605 oz., equal to 6·1 dwt. per ton. The par value of the gold was £2,872,542, equal to 26s. 1d. per ton. To this must be added £926,062 accruing from premium, equal to 8s. 5d. per ton. The total revenue was thus £3,704,273, equal to 33s. 8d. per ton. The working cost was £2,611,137, or 23s. 9d. per ton, leaving a working profit of £1,093,335, or 9s. 11d. per ton. The shareholders received £728,582, the dividend being at the rate of 77½%. The reserve is estimated at 8,131,700 tons, averaging 6·4 dwt. per ton, of which 4,972,800 tons, averaging 6·9 dwt., is in the Main Reef Leader, and 3,158,900 tons, averaging 5·4 dwt., is in the South Reef. Of this total, 1,289,000 tons, averaging 7·3 dwt., is in pillars and is not immediately available for stoping. The development of the large area below the 19th level is being actively conducted. No. 5A shaft has been sunk 1,573 ft. vertically below the 19th level main haulage east, and is now in readiness for the development of the area north-east of the South Rand dyke. Preparations are in hand for the sinking of No. 14A shaft below No. 14 vertical shaft, situated 2,000 ft. south of No. 5A shaft. This shaft is intended for the exploitation of the south-eastern part of the company's ground. The sinking of No. 15 shaft in the western section has been completed to the requisite depth, and the sub-shaft No. 15A is now in hand. The two shafts Nos. 14 and 15, with their continuations in depth, Nos. 14A and 15A, will be used in developing the extensive ground in the southern part of the property.

Meyer & Charlton.—This company belongs to the Albu group and works an outcrop gold mine in the central Rand. The report for 1920 shows that the remarkable prosperity of this comparatively small mine has continued, and owing to the premium has made a bigger profit than ever. The reserve of rich ore is, however, limited. During the year, 160,150 tons of ore averaging 13·16 dwt. per ton was mined and sent to the mill. The yield of gold by amalgamation was 39,649 oz., and by cyanide 45,010 oz.; in addition 17,503 oz. was extracted from concentrates. The total yield was 102,163 oz., equal to 12·77 dwt. per ton. The revenue from the sale of gold was £566,563, of which about

£133,000 came from premium. The working cost was £221,469, and the working profit £345,093. The revenue per ton was 70s. 9d., the working cost 27s. 7d., and the working profit 43s. 1d. The shareholders received £240,000, the dividends (Nos. 61 and 62) totalling 120%. The ore reserve is estimated at 450,050 tons averaging 14·1 dwt. per ton, as compared with 516,489 tons averaging 15·5 dwt. These figures do not include ore in pillars and hanging and foot-wall reefs; 54,555 tons was drawn from these sources during the past year

Geldenhuis Deep.—This company has worked a deep-level property in the near east Rand since 1893, and in later years absorbed the Geldenhuis outcrop mine. The control is with the Central Mining-Rand Mines group. The report for 1920 shows that 598,435 tons was raised, and after the rejection of waste, 557,500 tons averaging 5·93 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 104,101 oz., and by cyanide 52,093 oz., making a total of 156,194 oz., or 5·6 dwt. per ton. The revenue from the sale of gold was £861,944, of which £189,000 was premium. The working cost was £777,053, leaving a working profit of £84,891. The revenue per ton was 30s, 11d., the working cost 27s. 11d., and the working profit 3s. The shareholders received £87,862, the dividends being at the rate of 15%. The ore reserve is estimated at 1,467,100 tons averaging 6·1 dwt. per ton. Ore continues to be exposed in the western section of the mine, though of limited extent. In the eastern section many falls have taken place, and it is a question how long ore can be extracted safely. The life of the mine depends also on the gold premium.

Knight Central.—This company has worked a deep-level property in the middle east Rand since 1903, but little profit has ever been made. The control passed from Neumann's to the Central Mining-Rand Mines group three years or so ago. During the last two years the mine has been on the point of ceasing work on more than one occasion, but the gold premium together with new discoveries of limited extent have postponed the evil day. The report for 1920 shows that 295,100 tons of ore averaging 6·16 dwt. per ton was mined and sent direct to the mill. The yield of gold by amalgamation was 49,635 oz., and by cyanide 36,385 oz., making a total of 86,020 oz. or 5·83 dwt. per ton. The gold realized £470,697, of which about £108,000 represented premium. The working cost was £402,097, leaving a working profit of £68,600. The revenue per ton was 31s. 11d., the working cost 26s. 10d., and the working profit 4s. 8d. The shareholders received £67,500, being at the rate of 7½%. This is only the second dividend ever paid. During the year, 120,000 tons of ore averaging 5·9 dwt. per ton was exposed, and at the end of the year the reserve was estimated at 150,700 tons averaging 6·1 dwt. The development of the area south of the Simmer dyke between No. 4 and No. 5 incline shafts has given uniformly poor results. As regards the eastern part of the mine, further development would involve a large expenditure on a new incline shaft, and this expenditure is not considered to be warranted. The exploration of the large area on the dip could only be done by means of a new vertical shaft, which would cost far more than the funds at the company's disposal, and it would not be warranted by the prospects. It is not likely that the mine will survive the current year.

Witwatersrand Gold.—This company belongs to the Barnato group and works the Knight's mine in the middle east Rand. The report for 1920 shows that 463,055 tons of ore was delivered to the sorting station, and after the removal of 10% waste, 416,200 tons, averaging 5·8 dwt. per ton was sent to the mill. The yield by amalgamation was 87,615 oz., and by cyanide 29,011 oz., making a total of 116,626 oz., or 5·6 dwt. per ton. The revenue from the sale of gold was £650,133, of which £145,000 represented premium, and the working profit was £133,757. The revenue per ton was 31s. 3d., and the working profit 6s. 5d. The shareholders received £93,925, the dividends (Nos. 32 and 33) totalling 20%. The ore reserve is estimated at 774,500 tons averaging 6 dwt. per ton, as compared with 1,142,500 tons averaging 5·9 dwt. the year before. The sinking of the southern incline shaft has been stopped at a depth of 3,353 ft. as the prospects in the bottom of the mine are not promising. Toward the end of the year 47 claims were acquired from Knights Deep. It is hoped to obtain from these claims a substantial tonnage of ore which will help to keep the battery more fully employed than it otherwise would be.

Witwatersrand Deep.—This company used to belong to the Central Mining-Rand Mines group, but two years ago local shareholders obtained control. The report for 1920 shows that 369,597 tons of ore was raised, and this, together with 20,208 tons of low-grade ore from the dumps, was sent to the sorting station, where 5,885 tons of waste was removed. The ore milled was 383,800 tons averaging 5·53 dwt. of gold per ton. The yield of gold by amalgamation was 72,190 oz., and by cyanide 29,599 oz., making a total of 101,789 oz. The revenue from the sale of gold was £557,104, of which £136,404 came from premium. The working cost was £492,267, leaving a working profit of £64,837. The revenue per ton was 29s., the cost 25s. 8d., and the profit 3s. 4d. No dividend is paid, as funds are required for development and improvement in underground facilities. During the year the reserve has been increased from 922,639 tons averaging 6·4 dwt. to 1,018,390 tons averaging 6·3 dwt. The results obtained on the 24th level were on the whole disappointing, but conditions on the 25th level are better.

New Kleinfontein.—This company belongs to the Anglo-French Exploration group and works a group of outcrop mines in the Far East Rand. The report for 1920 shows that 667,392 tons of ore was raised, of which 93,070 came from the Benoni section, 16,652 tons from the Apex, and the remainder from the Kleinfontein. After the removal of 15% waste, 561,820 tons, averaging 6·08 dwt. per ton, was sent to the mill. The yield of gold by amalgamation was 104,212 oz., and by cyanide 57,665 oz., making a total of 161,877 oz., equal to 5·76 dwt. per ton. The revenue from the sale of gold was £875,490, or 31s. 2d. per ton, of which about £187,500 represented premium. The working cost was £798,991, or 28s. 5d. per ton, leaving a working profit of £76,498, or 2s. 9d per ton The shareholders received £57,577, the dividend being at the rate of 5%. The ore reserve is estimated at 1,623,574 tons, averaging 5·32 dwt per ton, as compared with 1,923,474 tons, averaging 5·61 dwt. the year before. In the Apex section, which is now closed, the reserve is estimated at 374,997 tons, averaging 4·98 dwt. The Apex mill is leased to Modderfontein East.

Modderfontein B.—This company belongs to the Central Mining-Rand Mines group and operates a gold mine in the Far East Rand. The report for the year 1920 shows that 614,736 tons was raised, and with 15,545 tons from the dumps, was sent to the sorting station. After the removal of 14% waste, 627,700 tons averaging 10·2 dwt. per ton was sent to the mill. The extraction of gold by amalgamation was 179,343 oz., and by cyanide 132,874 oz., making a total of 312,217 oz., or 9·95 dwt. per ton milled. The revenue from the sale of gold was £1,736,750, of which £438,304 came from premium. The working cost was £818,326, leaving a

working profit of £[illegible]18,423. The revenue per ton was 55s. 4d., of which 14s. represented premium, the cost 26s. 1d., and the profit 29s. 3d. The shareholders received £577,500, the dividends (Nos. 16 and 17) being at the rate of 82½%, while £144,814 was allocated to capital expenditure, chiefly on the two new southern shafts. The ore reserve is estimated at 3,006,600 tons averaging 8·6 dwt. per ton, as compared with 3,215,100 tons averaging 9 dwt. the year before. Development work has proved that much of the ground in the north-east area is disturbed by faults and dykes and unpayable. Most of the profitable ore exposed during the year was in the south-west area. The new south-east shaft was sunk to the reef, which is much disturbed here. Connection will be made with the rise put in from the Geduld in the south-east corner, where the ground is also disturbed, though a promising ore-body has been found. The south-west shaft is in course of sinking.

Government Gold Mining Areas (Modderfontein).—This company belongs to the Barnato group and works a gold mine in the Far East Rand. The report for 1920 shows that 1,763,913 tons of ore was raised, and after the rejection of 14% waste, 1,515,000 tons averaging 8·3 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 335,563 oz., and by cyanide 267,676 oz., making a total of 603,239 oz., or 7·96 dwt. per ton. The revenue from the sale of gold was £3,314,749, of which about £750,000 represented premium. The working profit for the year was £1,708,163. The revenue per ton was 44s. 9d., and the working profit 22s. 6d. The Government's share of the profits was £882,975, and £700,000 was distributed among shareholders, the dividends (Nos. 6 and 7) being 50% for the year. Development during the year has given excellent results. The reserve is estimated at 10,291,000 tons averaging 8·2 dwt per ton. Arrangements are in hand for making the south east shaft an upcast so as to improve the ventilation. Eventually it is expected that another shaft will have to be sunk for ventilation purposes only.

Van Ryn Deep.—This company belongs to the Barnato group, and works a gold mine in the Far East Rand. The report for 1920 shows that 750,606 tons of ore was raised, and after the removal of 22% waste, 583,950 tons averaging 10·58 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 198,387 oz., and by cyanide 107,441 oz., making a total of 305,824 oz. The revenue from the sale of gold was £1,677,474, of which about £375,000 represented premium. The working profit was £964,883. The revenue per ton was 54s. 6d., and the profit 33s. The shareholders received £777,979, the dividends (Nos. 14 and 15) amounting to 65%. The ore reserve is estimated at 3,260,000 tons, averaging 9·7 dwt. per ton. Development has recently been pushed in the western section of the mine, which has hitherto been neglected owing to the prospects being considered unpromising. The results have been encouraging, for though the ore is not of high assay value, still it is payable, and the reef widths are considerable.

Modderfontein Deep Levels.—This company belongs to the Union Corporation (formerly Goerz) group, and operates a gold mine in the Far East Rand. The report for 1920 shows that 635,414 tons of ore was mined, and after the removal of 20% waste partly below ground and partly on the surface, 507,700 tons averaging 10·82 dwt. per ton was sent to the mill. The yield by amalgamation was 171,524 oz., and by cyanide 96,348 oz., making a total of 267,872 oz., or 10·55 dwt. per ton. The revenue from the sale of gold was £1,466,594, of which £327,634 represented premium. The working cost was £575,287, and the working profit £891,307. The revenue per ton was 57s. 9d., the working cost 22s. 8d., and the working profit 35s. 1d. The shareholders received £725,000, the dividends being at the rate of 145%. As compared with the previous year, the revenue was 9s. 6d. per ton higher, the costs 4s. 3d. higher, and the profit 5s. 3d. higher. The reserve is estimated at 4,100,000 tons averaging 9·4 dwt. per ton, as compared with 3,775,000 tons averaging 9·1 the year before. A larger proportion of waste is now sorted out than formerly.

Geduld Proprietary Mines.—This company belongs to the Union Corporation (formerly Goerz) group, and works a gold mine in the Far East Rand. The report for 1920 shows that 637,276 tons of ore was mined, and after the rejection of 15% waste, 527,800 tons, averaging 7·63 dwt. per ton, was sent to the mill. The yield by amalgamation was 83,937 oz., and by cyanide 102,993 oz., making a total of 186,930 oz., or 7·1 dwt. per ton. The income from the sale of gold was £1,023,953, and the working cost £635,283, leaving a working profit of £388,673. The premium on gold accounted for £229,259. The yield per ton was 38s. 10d., the working cost 24s. 1d., and the working profit 14s. 9d. The shareholders received £205,296, the dividends being at the rate of 17½%. The developments have given good results, especially in No. 7 level east from No. 3 shaft toward No. 7 shaft, where a large amount of very high grade ore has been found. The reserve is estimated at 3,220,000 tons, averaging 8 dwt., as compared with 2,580,000 tons, averaging 7·4 dwt., the year before.

Brakpan Mines.—This company belongs to the Consolidated Mines Selection group, and has worked a gold mine in the Far East Rand since 1903. The report for 1920 shows that 699,019 tons of ore was raised, and after the removal of 14½% waste, 597,100 tons averaging 8·85 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 174,446 oz., and by cyanide 79,219 oz., making a total of 253,665 oz., equal to 8·5 dwt. per ton. The par value of the gold was £1,087,614, or 36s. 5d. per ton, and the premium brought an additional income of £336,164, or 6s. 11d. per ton. The working cost was £881,393, or 29s. 6d. per ton, leaving a working profit of £542,385, or 18s. 2d. per ton. Shareholders received £380,190, the dividends (Nos. 17 and 18) totalling 45%; £25,000 was placed to reserve for reorganization of plant and equipment, and £125,000 was allocated to expenditure on the new leased area. The ore reserve is estimated at 2,526,517 tons averaging 8·88 dwt. per ton, as compared with 2,484,000 tons averaging 8·74 dwt. the year before.

Springs Mines.—This company belongs to the Consolidated Mines Selection group, and was formed in 1909 to work gold-mining property in the Far East Rand. The report for 1920 shows that 569,963 tons of ore was raised, and after the removal of 18½% waste, 465,800 tons averaging 9·58 dwt. per ton was sent to the mill. The yield of gold by amalgamation was 97,293 oz., and by cyanide 110,843 oz., making a total of 208,136 oz. The par value of the gold was £881,421, or 37s. 10d. per ton, and the premium realized £271,503, or 11s. 8d. per ton. The working cost was £714,436, or 30s. 8d. per ton, and the working profit was £438,487, or 18s. 10d. per ton. The shareholders received £251,372, the dividends (Nos. 3 and 4) totalling 20%. The ore reserve is estimated at 2,726,178 tons averaging 8·76 dwt. per ton, as compared with 2,417,298 tons averaging 8·74 dwt. the year before. The increase is due chiefly to the further excellent development of the large ore-shoot in the east haulage area in the South Shaft district, but is also due to good results in the area contiguous to the north-west haulage.

EDITORIAL

THE coal strike has caused the power engineers to turn their attention to oil once more, and some of the railways and electric stations are thereby enabled to carry on. The Government has announced that all new ships built for the Navy are to use oil-fuel.

WE would draw attention to a communication, printed elsewhere in this issue, in which Messrs. H. W. Hutchin and Stanley B. White appeal for subscriptions to the Camborne Memorial to old students who fell in the war. Some particulars of the Memorial were given in our issue of January last.

AFTER having served its purpose well for twenty years, the Charters Towers School of Mines is to be dissolved. Owing chiefly to the decay of the local goldfield, but partly also to the general depression of mining operations in Queensland, there is little demand now for facilities in connexion with mining education. In future, such instruction will be given at the Charters Towers Technical College. During its comparatively short existence, the influence of the school has been felt throughout Australia, and its graduates have made good in many important positions.

PUBLISHERS of and subscribers to technical journals and proceedings of scientific societies were naturally alarmed at the proposal of the bureaucratic deadheads of St. Martin's Le Grand to double the postage on printed matter sent abroad. Fortunately the Government defeat in the Westminster election supervened, and the obnoxious decree has been withdrawn. The Postmaster-General, seeing the signs of the times, has appointed a committee of active business men of acknowledged standing, with whom he will confer before proposing any more modifications of the postal service. This is a distinct improvement in public policy.

A MILD sensation was caused last month by the announcement in the daily press that a Hatton Garden pearl merchant had been deceived by artificial pearls grown in Japan. The fact is that this "culture" has been known to scientists and to the market for some years. Mr. K. Mikimoto, the pioneer of this work, published a description and diagram of the process in his catalogue, and Dr. Lyster Jameson described it at the meeting of the British Association held in Dundee in 1912. Briefly described, the process consists of inserting a bead of mother-of-pearl in the oyster in a particular way and allowing the oyster to do the rest. We are not sufficiently versed in the art of casuistry to care to argue whether these pearls are really "pearls" or not.

ATTENTION is once more being drawn to Greenland and its possible resources by the celebration of the two hundredth anniversary of the foundation of a Danish colony there by Pastor Egede. The presence of the King and Queen of Denmark at Godthaab, Egede's little settlement, will serve to renew interest in the northerly outposts of civilization. Much is heard of Spitsbergen, and the coal deposits in Iceland have been the subject of discussion recently. The only mineral at present worked in Greenland is cryolite, which is required as a solvent for alumina in the electric production of aluminium. But most of Greenland is covered with the glacial cap and only a small coastal fringe is available for prospecting.

IT is surprising to hear that the Institution of Electrical Engineers is not yet in possession of a Royal Charter. In these days it is hardly possible for the casual observer to believe that electricity is a new thing, any more than a mining engineer can realize without reflection that Johannesburg had no railway communications until 1892. The Institution was formed originally as the Society of Telegraph Engineers, and in those days it applied for a charter. This application was, of course, opposed by the Institution of Civil Engineers, as all such proposals are. It seems strange that another application has been postponed so long, but presumably there will be no valid objection this time. Indeed, there seems to be some disposition on the part of the Council to truckle to the Civils, for the proposal is made that members shall be entitled to the exclusive use of the designation "Chartered Electrical Engineer," just as the Civils are now trying to establish a "Chartered Civil Engineer." This word "Chartered" does not seem to convey much distinction; it is too reminiscent of the proverbial "chartered libertine." If we have any grumble to make

against the Electricals, it is that they admit stockbrokers who may happen to be on the board of electrical companies to full membership of their Institution.

ELSEWHERE in this issue we print extracts from Dr. J. D. Falconer's Bulletin on the geology of the tinfields of the Bauchi Plateau in Nigeria. This is No. 1 of a series of bulletins in course of preparation by the Geological Survey of Nigeria, which was established in 1919, with Dr. Falconer as director and Captain R. C. Wilson as assistant director. The scientific staff was augmented in 1920 by the appointment as geologists of Messrs. C. Raeburn, F. Y. Henderson, and A. D. N. Bain. Dr. Falconer, together with Messrs. Raeburn and Henderson, have been chiefly engaged in mapping the tinfields, and Captain Wilson and Mr. Bain in exploring the railway belt. The extracts which we give comprise only a small portion of the bulletin, but they suffice to indicate the general geology of the plateau as now interpreted. Specific references to the rocks and alluvial deposits are omitted, and it has been impossible to reproduce the geological map. We have, however, drawn an outline topographical map, which will help in the reading of the article. As regards the merits of the bulletin, mining engineers will have no two opinions, for it is obvious that the information and the reasoning will be vastly helpful and encouraging to the manager and prospector. Dr. Falconer's book on the Geology and Geography of Northern Nigeria, published in 1911, written as a result of investigations made for the Colonial Office, was useful to the pioneer, though, as the author said, the ground covered was large and there was no great concentration on any particular line of investigation. The man in search of ore, wrongly impatient of geological studies of no immediate financial aid to him, did not appreciate that book in the way he should. However, he ought to be satisfied now, for the bulletin gives him just the information he desires. Dr. Falconer has substantially modified some of his views, after prolonged acquaintance with the tinfield, and after studying the evidence brought to light during the mining operations of the last few years. In this way he has been able to amplify the explanation of the geological history of the district, and to unravel the complicated succession of igneous and volcanic actions and intermediate erosions. Thus, he can give hopes for the discovery of many buried alluvial deposits likely to be rich in tinstone. Several mining engineers have already expressed views to this effect, and it is consequently gratifying to all interested in Nigeria that Dr. Falconer should accept this interpretation of Bauchi geology. As we have already said, it is impossible to quote Dr. Falconer in full in our pages. Engineers should read the complete bulletin in order to understand the matter fully. The bulletin is published by the Nigerian Government, but is obtainable at the Technical Bookshop of THE MINING MAGAZINE, at the price of ten shillings.

THE forty-fourth annual dinner of the old students of the Royal School of Mines was held on May 27 at Gatti's restaurant in the Strand, and, as usual, proved a highly successful function. The toast of the evening was proposed by Sir Edgar Walton, High Commissioner for South Africa. In reply, the President, Professor S. J. Truscott, called attention to the presence at the dinner of many official representatives of the Overseas Dominions, and took the opportunity of pointing out the strong and increasing interest taken by leaders of thought in all parts of the Empire in the scientific treatment of mining problems, and in the provision of modern educational facilities for training the rising generation in a manner adequate for the tackling of the ever-increasing difficult problems with which a mining engineer is faced. Mr. R. C. Griffith subsequently proposed the toast of the Guests, to which Sir James Allen, High Commissioner for New Zealand, and Mr. C. McDermid, Secretary of the Institution of Mining and Metallurgy, responded. Mr. McDermid arrested the attention of his hearers by giving some inside history of the saving of the Royal School of Mines and the creation of the Imperial College of Science and Technology. Let us say that the Council of the Institution collectively and Mr. McDermid individually have taken no small part in overcoming the inertia and indifference of the Government educational authorities and in bringing the Imperial College to a high level of efficiency and influence. While on this subject of the Institution's services to education, we would express the hope that the Council will before long take another step in assisting the educational cause by reinstating the post-graduate scholarships which were suspended

during the war. With mining in such a depressed condition, it may hardly seem to be an appropriate time for reviving this scheme, but it must be said that its abeyance partakes to some extent of the nature of a damper.

REVIEWING Lieutenant Smart's new book on breathing apparatus used in mine rescue work, Mr. Stanley Nettleton draws attention to the records in this book of noxious gases given off by explosives. Lieutenant Smart's experience was partly obtained at the Front, and partly in the mines, and he draws on much of his war experience for the benefit of the mining engineer. Of all the noxious gases mentioned by him, carbon monoxide is by far the most insidious and dangerous. It is deadly, and at the same time undetectable by the five senses. If it had not been lighter than air, it would have been the poison gas par excellence in warfare. And there is no antidote to carbonic-oxide poisoning, for its effect is to change the character of the blood in a vital manner without any hope of a reversal of the process. Lieutenant Smart mentions the opinion of certain authorities that the effect of the presence of this gas in the resultant fumes of explosive action in mines is to induce tuberculosis in the lungs. At the present time quartz spicules are bearing the blame for miners' phthisis, and the effect of poisonous gases is in the background. While writing of the deleterious effects of carbonic oxide, it is appropriate to mention that the towns' supplies of so-called illuminating gas now contains 20% of this poisonous gas. The gas delivered to our homes for lighting, heating, and cooking purposes is the rankest of poisons, and woe be to those who by inadvertence or carelessness permit its escape in unconsumed form. The source of danger is not by any means confined to the want of care on the part of the members of the household, for many stoves supplied by the gas companies are badly made and do not burn all the gas emitted, while there is always the danger of accidental leaks in pipes and fittings, and we are well aware of the deficient intellect of the ordinary plumber. No doubt those who read the reports of the coroner's courts know something of the alarming increase in gas poisoning recently. Reverting again to the quartz spicules, it will be remembered that various authorities have said that the ill effects of these spicules can be obviated by adding other dust to the air breathed into the lungs. At a recent meeting of the American Institute of Mining and Metallurgical Engineers, Dr. H. M. Landis gave evidence which goes to raise doubts on this subject. In speaking of the potter's phthisis, he said that the potter inhales clay dust in which there is a small amount of silica, and that in the course of years the potter's lungs get into the unsatisfactory state associated with silicosis. The conclusion is that silica is always the cause of the trouble, and that admixture with clay and similar harmless minerals tends to postpone the evil day. Thus the addition of other mineral dust to the mine air is only a palliative and not a certain prophylactic.

Central Mining and Investment

In the last issue a brief survey was made of the results of mining on the Rand, and of the present outlook there. Since then the report of the Central Mining and Investment Corporation has been published, containing a review by the Company's consulting engineer, Mr. Hugh F. Marriott, of the performances of the mines under the control of the Central Mining–Rand Mines group. Mr. Marriott's yearly reports are already well known for their directness and clearness of statement, and for their freedom from suppression or meretricious glozing of the less favourable circumstances. In the present report Mr. Marriott makes his primary calculations on the basis of the par value of gold, so that it is possible to see at a glance the influence of the premium on the current fortunes of the mines. He also gives full particulars of working costs, with comparative figures for the previous year. We extract from his report a few of the many interesting points.

The Central Mining–Rand Mines group controls no fewer than twenty mines operating on the Rand. Among these are found mines of all sorts of conditions and age. First in point of importance is New Modderfontein, which shares with Government Areas, of the Barnato group, the honour of being the greatest gold mine of the world. Its neighbour, Modderfontein B, is also a big producer, and another neighbour, Modderfontein East, is typical of the new work now being done in the Far East Rand under the adverse conditions of financial stringency. Crown Mines, City Deep, and Village Deep are celebrated large deep-level properties. Robinson is an ex-greatest gold mine of the world, just about at its

end ; East Rand Proprietary is one of the great low-grade consolidations, and it is struggling for its existence. Ferreira Deep and Wolhuter are old mines approaching exhaustion. Rose Deep, Geldenhuis Deep, Knight Central, Durban Roodepoort Deep, Consolidated Main Reef, and Nourse Deep live by the grace of the gold premium, at the present level of costs. Bantjes has given poor development results, and is closed. City and Suburban, New Heriot, and Village Main Reef are mines with excellent records, but are now entirely exhausted.

The gold output of this group during 1920 was worth £15,879,251, par value, or nearly one half (to be exact 47½%) of the Rand output, which was £33,231,257. The whole output of the world during 1920 was estimated at 70 million pounds, so it will be seen that Central Mining controls 28% of the world's production of gold. The aggregate working expenditure at this group of mines was £14,911,835, so that without the premium the working profit would have been only £967,416. The premium brought an additional revenue of £4,913,764, making the total profit £5,881,180, out of which £4,280,336 was distributed as dividends. The mines showing a working profit, exclusive of premium, were the following :—

	£
New Modderfontein	1,031,185
Modderfontein B	492,984
Crown Mines	209,603
City Deep	173,734
Modderfontein East	24,725
Ferreira Deep	32,287
Rose Deep	8,002
Total	1,972,520

It will be seen from the figures quoted here that the aggregate losses at par value were about one million pounds ; of the individual items, the largest were : East Rand Proprietary, £334,459 ; and Durban Roodepoort Deep, Geldenhuis Deep, Nourse Mines, and Village Deep, approximately £100,000 each.

Mr. Marriott analyses the figures for revenue, costs, and profits per ton milled, and shows that at the mines belonging to the group the average yield at par was 28s. per ton, average additional revenue accruing from premium 8s. 8d., total revenue 36s. 8d., working cost 26s. 9d., working profit at par 1s. 3d., working profit, including premium, 9s. 10d. There is also the item of taxation, over and above working cost, of 1s. 5d. per ton, so that taking gold at par there would have been a net loss of a few pence per ton. Mr. Marriott sees the chance of the cost of materials coming down, but does not hold out much hope for a reduction in white labour costs unless some drastic changes in conditions are introduced, and modifications made in certain obsolete mining regulations, which unduly restrict the hours of work of native labour and prevent the natives undertaking higher classes of work.

The Porphyry Coppers

Some elaborate tables have been published by Messrs. Hayden, Stone & Co., of Boston, giving particulars of the outputs, reserves, profits, and financial positions of the Jackling group of copper mines usually known as the "porphyries", or "disseminated coppers", namely, the Utah Consolidated, Nevada Consolidated, Chino, and Ray. These, with the Miami, Inspiration, and Arizona, constitute a class of copper mine by themselves, which depend for their success on the cheap mining of immense low-grade ore-bodies, in which the important copper mineral is chalcocite. Utah Consolidated has been producing since 1905, Nevada Consolidated since 1907, Ray since 1910, and Chino since 1911. They had a set-back at the outbreak of war, owing to foreign trade being dislocated, but afterwards the big war demand brought unwonted prosperity during 1917 and 1918. Subsequently the output had to be curtailed, and the figures for 1919 and 1920 are about half those of 1917 and 1918, and correspond virtually to those of 1912 or 1913. The costs have gone up during the past two years, and the price of copper has fallen, so that during 1920 the margin of profit became very narrow. Since the end of 1920 the position became worse, and, as already recorded in these columns, operations have been suspended at all the Jackling coppers.

It is quite impossible to reproduce the tables here owing to the exigencies of space. All we can do is to quote some of the items of interest, and recommend readers to apply for copies of the originals. At the Utah Consolidated the ore milled during 1920 was 5,556,800 short tons, averaging 1·16% copper, from which 101,897,758 lb. of metal was extracted, the recovery being 81·38%. At the Nevada Consolidated, 2,568,588 tons, averaging 1·45%, yielded 48,311,895 lb., the recovery being 70·2%. At Chino, 1,838,148 tons, averaging 1·76%, gave 44,051,849 lb., the recovery being 70·67%. At Ray, 1,706,928 tons, averaging 1·72%, gave

47,062,030 lb., the recovery being 82%. The percentage of recovery has improved considerably during the past two years at Utah and Ray, the 81 and 82% comparing with about 65% six years ago. The improvement is due to the introduction of flotation plant, and it is of interest to remark that the validity of the process used is still the subject of litigation. Apparently this system of concentration is not used at Nevada Consolidated or Chino, for the recovery figures do not show much variation. The improvement at Utah has been so substantial that it has been possible to maintain the output of copper, though the ore treated contained only 1·16% metal, as compared with 1·35%, the average of the reserve.

A study of the statistics relating to cost and price of copper per pound indicate the irregular nature of these items in base-metal mining. At Utah Consolidated the cost per pound shows a steady fall from the beginning of operations intil 1915, when the figure was as low as 6·6 cents. Subsequently it rose once more, advancing to 6·95 cents in 1916, 11 cents in 1917, 12·5 cents in 1918, and 13·1 cents in 1920. During the years 1916 and 1917 the prices obtained for the copper were 26·14 cents and 24·18 cents, figures far higher than any other recorded. It is not surprising therefore to find that the disbursements to shareholders for those years were 19½ million and 23½ million dollars respectively. During 1919 and 1920, the average was 17·7 cents in each case, so that the margin of profit was not great. At Nevada Consolidated the cost per pound in 1920 was 17·28 cents and the price realized 17·7 cents; at Chino, 14·4 cents and 17·4 cents; and at Ray, 15·5 cents and 17·5 cents respectively.

The reserves of ore at the four mines are best given in the form of a table :—

	Tons.	%
Utah Consolidated....	364,130,800	1·35
Nevada Consolidated .	63,845,631	1·58
Chino	105,689,247	1·53
Ray	83,004,043	2·06

The reserves are not quite so high at Utah as they were four years ago, the new ore added being about half the amount of ore mined; the same may be said of Nevada Consolidated. For the last five years no new ore appears to have been brought in at Ray; on the other hand, considerable additions have been made to the reserve at Chino.

As a companion table to that dealing with ore reserves, we give herewith figures for the tonnage treated and the copper produced from the beginning of operations at each mine. The dates of commencement have already been given.

	Ore. Tons.	Copper. Short Tons.
Utah Consolidated....	89,340,223	773,076
Nevada Consolidated .	35,180,801	379,840
Chino	21,490,415	255,156
Ray	23,522,127	279,766

The disbursements to shareholders since the beginning, together with the surplus at the end of 1920, are given in the following table :—

	Total Disbursements. $	Surplus at end of 1920. $
Utah Consolidated....	111,509,662	44,177,422
Nevada Consolidated .	46,768,616	6,537,602
Chino	29,991,709	13,889,908
Ray	25,412,620	14,264,228

Messrs. Hayden, Stone & Co.'s circular also contains some general figures relating to the copper position in the United States. The unsold stock of copper in the United States is estimated as at April 15 at 362,500 short tons; the figures given for the output, domestic consumption, and export for 1913, 1918, and 1920 are as follows :—

	Short Tons. 1913.	Short Tons. 1918.	Short Tons. 1920.
Output	810,000	1,177,500	832,500
Domestic Consumption	382,500	740,000	622,500
Exports	437,500	377,500	242,500

These indicate at a glance the inability of foreign customers to buy American copper, and the fact that the United States has been able to consume much more copper in 1920 than in 1913. It would appear that the slump in 1921 has been caused, not so much by any further fall in exports, but by a slackening of domestic demand.

As regards cost of production throughout the United States, the figure for 1920 is given at 15·5 cents per pound, for 1918, 15·47 cents, and for 1913, 10·5 cents. The estimated average prices for the same years were 17·46 cents, 24·63 cents, and 15·27 cents respectively. The price at April 15, 1921, was 12·75 cents, a price below the average cost of production, and one which indicates a serious fall in demand. That so many mines should have closed, and no improvement since have occurred in the price, shows how dead the market is and to what a low level consumption has fallen. The cut in wages in the manufacturing industries in America may revive the demand, but the producers are still looking in vain for an improvement in foreign business.

REVIEW OF MINING

Introduction.—The general situation remains much the same as last month. The coal strike continues, and efforts are still being made to find a way out of the difficulty. In the meantime other industries have been brought to a standstill. In the Lancashire cotton trade the position is almost identical with that in coal mining, the employees objecting to the big cut in wages proposed by the mill-owners. As regards metal mining, the chief item of importance is another sudden drop in New York exchange, the effect of which has been to send the gold premium up again.

Transvaal.—The cost of mining has provided the subject for many addresses by chairmen of mining companies during the last month. Mr. Walter McDermott, in his speech at the meeting of shareholders of the Consolidated Mines Selection, held in London, went bald-headed for the agitators who apparently want the business of the world to come to a standstill. In the case of this company, orders for necessary new machinery cannot be filled in this country, owing to the coal strike and the concomitant paralysis of the steel industry, and, in default of any other resources, the machinery has been obtained from Germany. One of the shareholders expressed a doubt as to the advisability of Mr. McDermott making this attack on labour, but the sense of the meeting was soon seen when another shareholder expostulated in no uncertain words with the first shareholder for his timidity and his disinclination to meet the labour agitators face to face. The result was that Mr. McDermott was thanked by the whole meeting for his courageous stand.

Another speech of importance in this connexion was made by Mr. Samuel Evans, in his capacity as chairman of the Crown Mines, at the meeting held in Johannesburg. He expressed his opinion that prices of materials and labour would fall to such an extent during the next few years that the costs of all operations, including mining, would soon reach a low level. He was sufficiently optimistic to believe that before long it might pay Crown Mines to start from the outcrop of the Main Reef once more and work 3 dwt. ore.

Elsewhere in this issue we quote Mr. H. F. Marriott's analysis of the results for 1920, and his views as to the future of Rand mining contained in his report to the Central Mining and Investment Corporation. We also print in full Sir Lionel Phillips's speech to shareholders of Central Mining.

The crank-shaft of the hoisting engine in the Driefontein section of the East Rand Proprietary Mines broke on June 1. If a suitable shaft can be obtained locally, the period of idleness will not be more than a fortnight.

The report of the Transvaal Consolidated Land and Exploration Co. contains some particulars of the company's tin operations in the Northern Transvaal. The Groenfontein mine made a profit of £13,208 during 1920, but it is now closed temporarily owing to the low price of tin. The Mutue Fides mine is exhausted, after having yielded satisfactory profits on a small scale. At Witfontein the early promise did not endure, and prospecting work has been discontinued. The Welgelegen prospect is giving encouraging results, and so is Allemansdrift.

Cape Province.—A scare was started last month in the daily press to the effect that De Beers Consolidated was about to make a new issue of debentures, and the public consequently feared that the diamond position was unexpectedly serious. When the official announcement was made, the proposed issue was found to be in connexion with the Cape Explosives Works, Ltd., which operates the explosives factory near Cape Town, founded by De Beers, and subsequently becoming famous owing to the distinguished technical management of Mr. W. R. Quinan and Mr. Kenneth Quinan. These works have been considerably extended recently, the funds being advanced by the De Beers Company. The issue of the debentures of the Cape Explosives Works, Ltd., was made for the purpose of repaying De Beers for the loans. It is of interest to note that the extension of the works was in connexion with the manufacture of other articles than explosives. Superphosphate of lime and a number of other fertilizers are now being made, as well as many other chemicals used in agriculture and cattle raising. The debentures were eagerly subscribed by the public.

Work at the Namaqua Company's copper mines continues to be confined to exploration and development owing to the conditions not favouring a resumption of smelting. The results have been gratifying, and the reserves have been substantially increased, particularly at the Homeep property. The

total reserves at the various mines is estimated at 63,200 tons, averaging 7% copper. Of recent years the company used to produce a matte and ship it for treatment elsewhere. Present economic conditions would not admit of this course, so the directors contemplate the erection of a converter plant.

West Africa.—In a recent issue it was recorded that the Ashanti Goldfields Corporation is changing over from dry to wet crushing, on account of the great scarcity of fuel required for roasting the ore, the new plan consisting of wet crushing, concentration, and the roasting and cyaniding of concentrate. A report issued by the company last month states that Mr. W. R. Feldtmann, the consulting engineer, has visited the mines, and has made the necessary arrangements for the alteration in practice. The new plant is now in course of erection. In regard to the fuel question, the company was fortunate in being able to secure 2,000 tons of Welsh steam coal and ship it just before the strike. It is believed that this coal will so supplement the present local wood supplies as to keep things going until the wet crushing and concentration plant is ready.

Nigeria.—The Keffi Consolidated Tin Co. is to absorb the Associated Nigerian Tin Mines. These two consolidations were formed last year and in 1919 respectively, and particulars were given in this column at the time. The expanded company owns extensive properties on the Bauchi Plateau. The directors intimate that they are concerned in the financing of a hydro-electric power scheme. We take this to mean that they are coming to the rescue of the Northern Nigeria (Bauchi) installation, the completion of which was prevented by inability to raise the necessary additional capital.

The Naraguta (Nigeria) Tin Mines, Ltd., has issued a circular containing a report by the general manager, Mr. F. O'D. Bourke, covering a report by Mr. Clyde Allan, which gives some particulars of prospecting and development operations on the gold lodes of Birnin Gwari. It was assumed by the market that this report referred to absolutely new discoveries. As a matter of fact, the occurrences have been known for many years. Dr. Falconer, in his book published in 1911, refers to quartz veins and alluvial gold in this district, and he gives many suggestions as to opportunities for prospecting for gold-bearing lodes. He also refers to alluvial gold being found in association with tin on the Bauchi Plateau, a subject which has been revived in the mining market since the Naraguta circular was issued. Mr. Clyde Allan's report deals with the tracing of lodes below the alluvium, and some of his results may be considered to be quite promising.

The report of the Nigerian Tin Corporation for the 21 months ended December 31 last reflects the unsatisfactory position of the tin industry in Nigeria. The company is not a large producer of tin, its activities being more on the financial side. The output yielded £13,885, against an expenditure in Nigeria of £19,338. Tin mining has since been suspended. Dividends, commission, interest, and profits on realization of investments brought an income of £15,153, and after the payment of London expenses, a net profit of £4,617 remained. The company is controlled by Mr. Oliver Wethered, and it has large interests in many Nigerian, Cornish, and Malayan tin companies.

Australia.—The attempts of various companies to induce their men to accept lower wages and speed up the work all appear to be doomed to failure. The men may be agreeable, knowing the circumstances, but all their negotiations have to be conducted by the unions, who care little for either master or men. Thus at Mount Lyell the board's proposals for reduced wages have been rejected, so that all operations are to be suspended on June 16.

The directors of the Bullfinch Proprietary have placed the management of the mine in the hands of Bewick, Moreing & Co., who will inaugurate a limited scheme of development for the purpose of finding payable ore.

A report by Mr. J. B. Lewis has been issued on the Federation Tin Company's properties at Mount Heemskirk, on the west side of Tasmania. As there is a movement on foot for raising further working capital in England, some particulars of the property will be of interest. The granite is intersected by many lodes of varying mineralogical composition, all characteristic of the usual intrusions of residual matter following the granite flow. Twenty lodes from 2 ft. to 30 ft. in width have been sampled, and have been proved to contain ½% and upwards of tin. Sufficient work has been done on eight of the lodes to warrant an estimate of the reserves. Mr. Lewis gives the figure at 57,700 tons, averaging over 1%, with the probable ore at 450,000 tons. The district was originally discovered in 1875, and work

was done intermittently in 1880, 1893, and 1903, but owing to the small scale of operations the financial results were not satisfactory. There is now a battery of forty stamps on the spot. A dam has been built across the valley, and a hydro-electric station is to be erected. It is believed that under these conditions excellent profits will be made when tin recovers.

India.—The Gersoppa falls, in Mysore State, are to be utilized for the production of hydro-electric power, the Government of the State having the matter in hand. The falls are 830 ft. high, and the power-house is to be 150 ft. below the bottom, so that a head of over 1,000 ft. will be obtained. A dam is to be built above the falls. This will be 120 ft. high, and the reservoir so formed will have a capacity of 42,000,000,000 gallons. It is estimated that 100,000 h.p. will be generated.

Burma.—The Burmah Oil Company is about to issue £3,000,000 8% preference shares, which are part of £5,000,000 new preference shares authorized at a meeting held in Glasgow on June 1. The directors also proposed that the two existing series of preference shares should be consolidated, and the rate of interest raised to 6½%, but the votes in favour did not give the necessary three-quarters majority. Why so many shareholders failed to send their proxies is not quite clear.

Malaya.—The Idris Hydraulic Tin Company reports a yield of 263 tons of tin concentrate during 1920. This and tributers' ore brought an income of £46,979, and the profit admitted of the payment of £18,000 as dividend, being at the rate of 15%. As is the case with most other Malay tin mines, little or no curtailment of output has been made since the serious fall occurred in the price of the metal.

Cornwall.—A serious accident at East Pool occurred last month, resulting in the choking of the main hoisting shaft at about the 130 fathom level. At this point the shaft runs through an old stope, and it was the collapse of this stope that caused the blockage. It is too early to estimate the actual amount of damage done.

The only Cornish tin mines which have so far weathered the gale of adverse circumstances and kept running are the Giew mine of the St. Ives Consolidated Mines, and the small privately owned Magdalen mine at Ponsanooth. As neither of these can boast of anything remarkable in the way of mineral riches, their continuance in active operation is surprising, and creditable to those in control.

At the Kingsdown mine, near St. Austell, the new main shaft has been sunk and timbered to 220 ft., and the erection of the pumping and hoisting plant is in hand. Development below water level will be commenced forthwith. The lease of the adjoining Ventonwyn property has been secured.

Particulars of Cornish Kaolin, Ltd., have been published during the past month. As has already been mentioned in these columns, the company was formed in 1912 to work china-clay deposits on Bodmin Moor, on lease from Lord Clifden's estate. This estate now belongs to Tehidy Minerals, Ltd., and the mineral rights were acquired by the company when the control was purchased recently from the original operators. Messrs. Bewick, Moreing & Co. are the general managers, and the necessary working capital has been subscribed by the Sons of Gwalia, Ltd., East Pool & Agar, Ltd., and Tehidy Minerals, Ltd. The previous operators had developed the Glynn Valley property, and had built a pipe-line to Bodmin Road Station, where a dry was erected. Since the change in control, further deposits of clay have been proved, and arrangements have been made for increasing the rate of output.

United States.—Further curtailment of copper output has taken place, among the mines closing recently being the Copper Queen and the mines of the Arizona Copper Company.

The Anaconda Copper Mining Co. mined 2,152,760 tons of ore during 1920, a figure considerably below normal, but an increased amount of exploratory and development work was done, with very satisfactory results. At the copper smelters 2,319,336 tons of ore and precipitate was treated, of which 1,828,379 tons came from the company's mines, 458,339 tons was purchased or custom ore, and the remainder precipitate and cleanings. The total copper produced was 155,339,575 lb., the silver 7,113,659 oz., and the gold 32,530 oz. The leaching plant treated 484,352 tons of tailing and 43,271 tons of purchased ore, and the yield of copper precipitate was 5,037 tons. The zinc plants treated 310,572 tons of the company's ore and 133,010 tons of purchased material. The yield was 101,332 lb. of electrolytic zinc, together with

5,255,152 lb. of zinc in dross, and residue from which were produced 12,536,088 lb. of lead, 2,173,080 lb. of copper, 2,073,348 oz. of silver, and 6,150 oz. of gold. The net profit for the year was $2,691,660, and the dividends, partly paid out of surplus, absorbed $6,993,750.

Canada.—The following table gives the output of metals and minerals in Canada during 1920:—

Metallic.		
Cobalt, metallic and contained in oxide, etc.	Lb.	593,920
Copper	Lb.	81,155,360
Gold	Oz.	766,912
Iron, pig, from Canadian ore	Tons	75,869
Iron ore, sold for export	Tons	7,855
Lead	Lb.	33,985,974
Nickel	Lb.	61,136,493
Platinum from alluvial sands	Oz.	17
Platinum, palladium, etc., from Sudbury matte	Oz.	1,922
Silver	Oz.	12,793,541
Zinc	Lb.	40,166,200
Non-Metallic.		
Actinolite	Tons	100
Arsenic, White, and in Ore	Tons	2,408
Asbestos	Tons	167,731
Asbestic	Tons	20,956
Chromite	Tons	10,500
Coal	Tons	16,623,598
Felspar	Tons	36,856
Fluor-spar	Tons	11,229
Graphite	Tons	2,227
Grindstones	Tons	2,319
Gypsum	Tons	429,144
Magnesite	Tons	18,373
Magnesium Sulphate	Tons	1,855
Mica	Tons	2,150
Natural Gas	M. Cu. Ft.	16,961,284
Oxides	Tons	18,768
Peat	Tons	3,900
Petroleum, Crude	Barrels	196,937
Pyrites	Tons	174,744
Quartz	Tons	127,995
Salt	Tons	210,211
Sodium Sulphate	Tons	813
Tripolite	Tons	260

Dr. Mackintosh Bell, manager of the Keeley silver mines, situated near Cobalt, cables to the effect that on No. 9 vein the ore averages 150 oz. silver per ton over 3 ft. for a distance of 65 ft. Toward the end of this development the silver is contained in two separate veins which average 300 to 3,000 oz. per ton over 2 to 10 in. This is the best report yet received from the mine.

Mexico.—The official estimate of the output of gold and silver during 1920 gives the gold figure at 750,000 oz. and that of silver at 63,750,000 oz.

Colombia.—During the latter half of 1920 the Frontino and Bolivia company treated 15,320 tons of ore, yielding 10,665 oz. of gold, the extraction being 13·92 dwt. per ton. The development has given disappointing results at several places and the reserves, at 58,200 tons, show a decrease of 7,500 tons. At the Marmajito, which is being reopened by a subsidiary company, the pumps and other machinery have been delivered, and it is expected that pumping will commence in July.

Trinidad.—The General Petroleum Company of Trinidad, Ltd., is absorbing the Amalgamated Oilfields of Trinidad, Ltd., the Anglo-Trinidad Oil Co., Ltd., and the San Francique Oil Co., Ltd. These companies are all under the same control. Sir Clifford Cory and Mr. Herbert Guedalla are joining the board of the expanded company, and Messrs. Cory Brothers and Co., Ltd., the South Wales shipping and coal firm, have the contract for the marketing of the oil. The drilling campaign was started recently, and the first well yielded oil on May 12, at a depth of 900 ft., the flow being over 150 barrels per day.

Venezuela.—The British Controlled Oilfields, of which Mr. D. Elliott Alves is president, and Sir E. Mackay Edgar vice-president, has issued an interim report. In the western division of the Buchivacoa section drilling is being done over 40 miles, six wells having been drilled or being in course of drilling. One of these has been flowing intermittently for fifteen months. No. 2 well has reached the upper oil sands at 630 ft. In the eastern division two wells are being drilled and another is to be commenced. No very definite results appear to have been obtained so far in any part of Venezuela by the company's engineers. Rights over a number of islands in the Orinoco delta have been acquired, and Mr. G. B. Reynolds has examined part of the property, indicating suitable places for drilling. Brief particulars are also given of work in Trinidad and Ecuador. Geological examinations are being made in Colombia and Costa Rica. The company also has concessions in other parts of Central America, where Mr. B. F. N. Macrorie is to make investigations.

Spitsbergen.—The Scottish Spitsbergen Syndicate announces that arrangements are in hand for forming a subsidiary company to develop its proved coalfields in the Klaas Billen Bay area. It has been decided to continue the investigation of other coal-bearing districts, and for this object a small expedition has been sent to the islands this spring.

NIGERIAN GEOLOGY

A STUDY OF THE ROCKS AND SURFACE DEPOSITS IN THE CENTRAL TIN-PRODUCING DISTRICT OF THE BAUCHI PLATEAU

By J. D. FALCONER, M.A., D.Sc.,
Director of the Nigerian Geological Survey

We present herewith, by permission, a brief résumé of Bulletin No. 1 of the Geological Survey of Nigeria.

Introduction.—The area over which the tinstone is distributed in Northern Nigeria lies at an average elevation of 2,000 ft. above the sea. It includes, however, the plateau of western Bauchi, which rises to an elevation of over 4,000 ft., is bounded on the north, west, and south by a more or less dissected escarpment, but on the east slopes gently downward to the plains of the Gongila. The richest deposits of tinstone have so far been found on and around the Bauchi plateau, and the tinfields as a whole may be subdivided into three sections :

(1) The Plateau Tinfields of Bauchi Province.

(2) The Northern Tinfields of Bauchi, Kano, and Zaria Provinces.

(3) The South Western Tinfields of Nassarawa Province.

The present Bulletin deals with an area of about 1,800 square miles, extending from the Delime valley in the north to the margin of the closed country in the south, and including the northern front of the plateau and the whole of that portion of the plateau over which tinstone is now being won. No account is given of the extreme southern portion of the plateau, which is also tin-bearing, but which is at present closed to prospectors for political reasons.

General Geology.—An ancient crustal complex of gneisses, schists, and gneissose granites has been invaded by a younger granite batholith, the higher portions fo which have been, in course of denudation, exposed at the surface and now appear as a series of detached stocks, bosses, and dyke-like masses separated from each other by more or less extensive areas of older rocks. Upon the plateau itself seven main outcrops of younger granite have been recognized. These may be termed : (1) Bukuru-Shere ; (2) Rukuba-Buji ; (3) Vom-Ganawari ; (4) Jarawa-Fusa ; (5) Forum ; (6) Ropp-Dress ; (7) Sha. The Bukuru-Shere and Jarawa-Fusa outcrops are connected at the surface by a number of narrow necks or bars of granite porphyry. Otherwise the various outcrops are entirely separated from each other.

The younger or "plateau granite" is typically a medium-grained biotite granite, pink, red, white, or yellow in colour from the prevailing tint of the felspars. It varies somewhat in texture, becoming in places finer grained or coarser grained than normal. It varies also in the amount of biotite it contains, while in some places riebeckite or soda hornblende replaces biotite. Marginally the granite tends to pass into a granite porphyry with felspar and quartz crystals set in a matrix of fine-grained granite rich in biotite. At its junction with the older rocks the granite usually becomes fine grained and microgranitic, occasionally micrographic or felsitic, with scattered porphyritic crystals and knots of quartz and pegmatite.

Associated with the granites and marking one of the later stages of igneous activity is a series of basic and acid dyke rocks. The basic types are mainly fine-grained basalts and dolerites, which, while most abundant outside of and on the margins of the granites, are also found in the interiors of the outcrops. The acid types include many varieties of felsite and quartz-porphyry.

After consolidation the younger granite was much broken and fissured. Along some of the fissure lines movement took place and gave rise to definite crush structures. More generally, however, the fissures formed lines of egress for vapours and solutions from the igneous focus, with the result that in places the granite suffered considerable alteration and mineralization along and in the neighbourhood of the fissure lines. The alteration was mainly in the direction of greisenization and silicification with addition of topaz and tinstone.

The older rocks which the younger granite invaded are of many and varied types. There would appear to have been originally occupying the site of the plateau a series of metamorphic rocks of mixed sedimentary and igneous origin into which two types of gneissose granite were injected. No mineralization accompanied these earlier intrusions, and no metamorphism of the older rocks took place as the result of the

injection into them of the younger granite. In places, however, the older rocks were altered by pneumatolytic action in the same way as the younger granite.

After the close of igneous activity long ages of denudation supervened, during which the older rocks were attacked and worn away and the upper surface of the younger granite batholith gradually exposed. The covering of older rocks has not yet been entirely removed, with the result that considerable stretches of the older series still separate the various granite outcrops, while in places detached masses of older rock can be seen still adhering to the surface of the granite. The upper surface of the batholith was probably highly irregular and the major irregularities on the surface of the plateau probably represent much reduced fangs of the younger granite which originally projected upward from the general surface of the batholith into the overlying rocks.

Where the covering of older rocks has been completely removed, a considerable portion of the superficial layer of the granite outcrops has also disappeared. It is believed that this upper layer of granite and, doubtless, also the older rocks immediately overlying were in places highly mineralized, indication of such mineralization being still apparent in the granites. In the course of denudation, and before the elevation of the plateau, the tinstone from the mineralized areas became gradually concentrated in stream channels on and around the granite outcrops, and possibly as the result of crustal warping and consequent drainage changes, became buried beneath a series of alluvial, eluvial, and volcanic accumulation, for which the name of Fluvio-Volcanic Series is suggested, as descriptive of their most typical development. With the elevation of the plateau, probably in Mio-Pliocene times, the whole surface was subjected to renewed erosion. New drainage lines were established on the plateau and the older superficial deposits in great part removed, while their tinstone content was rearranged along the floors of the present valleys. There still remain, however, considerable areas of the older Fluvio-Volcanic Series, mainly along certain primary and secondary watersheds, forming narrow stretches of high plateau or picturesque groups of flat-topped hills.

At some time during the recent period of erosion volcanic activity again broke out, with the result that large areas of the plateau were flooded with basaltic lava, which not only filled the valleys and covered up the tin-bearing deposits on their floors, but doubtless also obscured many partially eroded portions of the earlier Fluvio-Volcanic Series.

Origin of the Tinstone.—Throughout the areas surveyed, tinstone has nowhere been found disseminated through the plateau granite as a primary constituent. That it may occur locally as such is, however, probable from the fact that at Forum River tinstone occurs in the quartz knots of a marginal granophyre. This implies that small quantities of tin were present in the original magma, and that during the consolidation of the outer layer it was segregated along with the residual silica into miarolitic or crystallization cavities in the marginal granite. Incomplete segregation would result in the dissemination of small crystals of tinstone through the granite. A similar process may have been operative during the consolidation of the interior of the batholith.

So far as can be judged, however, from the area surveyed, this would appear to have been only a minor source of the tinstone of the plateau tinfields. There is little doubt that the greater part of the tinstone is of pneumatolytic origin, and was originally contained in lodes and veins and in mineralized streaks and patches in the outer shell of the batholith and in the older rocks immediately overlying. There is some evidence for the assumption that a highly mineralized belt 4 or 5 miles in width formerly extended from north to south across the Bukuru-Shere massif from the neighbourhood of Jos to the vicinity of Kuru. Throughout this belt there are abundant quartz leaders and veins, and streaks and patches of altered granite frequently carrying tinstone. Loose sub-angular fragments of lode tin of considerable size and weight are frequently found in the surface wash, while the richest alluvial deposits of the Bukuru-Shere massif occur on either side of this belt, which appears to have shed tinstone both to the east and to the west. Throughout the belt alteration and mineralization appear to have followed indifferently joints, fissures, and other lines of weakness running north and south, east and west, and in intermediate directions. A somewhat similar, but less extensive mineralized belt runs north and south through the Ropp massif in the neighbourhood of the Dome. Veins and stringers of cassiterite quartz occur in the older rocks

most frequently in the neighbourhood of the granite margins but sometimes at a considerable distance from them. On the hypothesis that the younger granite may everywhere underlie the older series, where only the latter appears at the surface, there is every probability that the gneisses and schists may in places be highly mineralized. The attempts which have hitherto been made to open up known occurrences of tinstone in the granites and gneisses have proved unsuccessful, but careful prospecting may yet reveal workable lodes, pipes, or stockworks within the rocks of the plateau.

The minerals which have been found in place in existing veins and altered rock include, besides tinstone, topaz and specularite, which are widely distributed, wolframite around Bukuru, near the Dome in the Ropp group, and on the Gwini River in Rukuba, pyrite and chalcopyrite near Jos, galena near Jos and at South Ropp, arsenopyrite on the Jarawa River, and molybdenite near Jos and in the Jarawa Hills. Fluor-spar occurs very sparingly in two localities near Jos, but it is an almost constant accessory mineral of the granite in microscopic crystals. The large crystals of tinstone and topaz with one perfect termination, which are frequently found in the surface wash, have probably been disintegrated from vughs in veins and lodes which have now been removed by denudation. Topaz and mica are the only minerals which have been formed by pneumatolytic action. The complete absence of tourmaline from the younger granite and its pneumatolytic products points to a general deficiency of boron in the original magma, its place having been taken by fluorine, which gave origin to the fluo-silicate, topaz, in place of the boro-silicate, tourmaline. Tourmaline pegmatites, however, are commonly associated with the older rocks, but on the plateau they have not yet been found to be stanniferous.

Fluvio-Volcanic Series.—From the date of the granite intrusion to late Tertiary times there is no evidence of recrudescence of activity in the igneous focus. As the result, however, of long ages of denudation, the cover of older rocks was largely removed and the underlying granite partially exposed. The earlier stages in this process of denudation can no longer be traced. It is probable that there were in the past repeated oscillations of the crustal surface, repeated variations in the rapidity of denudation, and many alternations of periods of erosion and periods of accumulation. During the periods of erosion the tinstone disintegrated from the granites and gneisses was accumulated in the river beds and stream channels, while during the periods of accumulation the valleys were infilled with gritty and earthy wash to such an extent that on the renewal of erosion the rivers frequently formed for themselves new channels over the surface of the land. Owing to the recent elevation of the plateau the present is naturally a period of erosion, but traces of one of the more recent periods of accumulation still remain in the Fluvio-Volcanic Series of the plateau.

It is presumed that during the period of crustal instability which preceded the elevation of the plateau, the transporting power of the rivers was reduced, probably through surface warping, and conditions became favourable for the accumulation of detritus over the site of the plateau. The ancient valleys with tinstone along the stream lines were infilled with river and rain-wash and volcanic material, and the minor irregularities of the surface obliterated by a mantle of debris (the Fluvio-Volcanic Series), which may have reached in places a thickness of 200 ft.

The constitution of the mantle is very variable. Its predominant constituent is a red gritty earth, varying much in the proportions of angular quartz and earthy material. It may be white, yellow, purple, or brown in colour, and streaked, banded, or mottled according to the amount and distribution of the iron oxide. As a rule the colouring becomes more intense towards the summit of the series. Concretionary knots and bands and lenticles of clay ironstone are common, and the more gritty bands are often compacted with a ferruginous cement. These gritty earths probably represent decomposed granitic and gneissic wash, possibly mixed with some volcanic material; their content in iron being due in part to the decomposition of ferruginous and ferro-magnesian minerals originally enclosed in the wash, and in part to the precipitation of iron oxide from ferruginous solutions circulating at a later date through the wash under conditions somewhat different from those existing during the period of accumulation.

Associated with these gritty earths are beds of fine grained, compact, kaolin clays, white, pink, or lilac in colour, breaking with a conchoidal fracture, and containing

occasional knots of quartz. These probably represent original accumulations of felspathic mud in pools of standing water in areas of uncertain drainage.

Also associated with these gritty earths are beds of soft yellow, blue, red, purple, or mottled earths of a peculiar fariniform texture, homogeneous throughout, entirely free from quartz, breaking with an even fracture and occasionally showing traces of a spheroidal structure. Sometimes, as in Kwi Hill they present a vesicular character with the vesicles arranged irregularly or in parallel series. Microscopic investigation has shown that these represent thin beds of entirely decomposed basaltic or doleritic lava, which flowed over water-logged plains during the period of uncertain drainage, and were covered up by further accumulations of rain and stream wash and rapidly decomposed. The alkalis, lime, magnesia, and iron appear to have been largely leached out of these earlier basalts, leaving pseudomorphs of felspar in amorphous hydrated silicate of alumina. Small quantities of gibbsite or hydrated oxide of alumina are occasionally present, especially in the vesicles, and Dr. Morrow Campbell has figured a decomposed dolerite from Monguna, in which the replacing material is mainly gibbsite.

With the basaltic earths are associated reddish earths of similar texture, but showing traces of a brecciated structure and containing a small amount of angular quartz. These are probably beds of much decomposed volcanic ash, the quartz having been an original constituent torn from the walls of the volcanic pipes. The foci from which this material and the associated lavas were emitted are naturally difficult to locate, but it is possible that some of the isolated pipes or plugs of basalt which are found throughout the western gneissic area may represent these older vents.

In this connexion it is interesting to note the occurrence and contents of what appears to have been an ancient volcanic pipe, discovered in the course of drilling operations on the Lower Gona. All traces of the pipe and of its accompanying volcanic accumulation have been removed from the surface, which is now covered to a depth of 90 to 130 ft. with recent alluvial deposits. In the pipe itself the uppermost 320 ft. consist of the usual sands and clays, but from 320 to 350 ft., the limit of the bore-hole, the pipe is filled with fragments of both vesicular and compact basaltic lava in a matrix of basaltic debris mingled with angular quartz grains and fragments of granite and gneiss. If material of this kind had been originally spread out on the surface and then weathered and decomposed, the result would have been a gritty brecciated earth very similar to that described above.

This mantle of gritty earths, clays, and volcanic material would naturally cover up the earlier stream-beds with their accumulations of tin-bearing wash, as well as the earlier detrital deposits on the slopes of the buried valleys. The general aspect of the country at the close of the period of accumulation would be very similar to that of the plains of Zaria at the present day, with occasional knobs, hummocks, kopjes, and groups of hills projecting from the general level, while the solid rocks below their mantle of water-logged debris would themselves be decomposed and whitened or kaolinized to irregular depths. On the higher portions of the surface, and wherever free oxygen could penetrate, iron oxide would be precipitated above the ground water level.

There followed the elevation of the plateau and the consequent renewal of erosion. New drainage lines were established and the mantle of debris rapidly removed from large areas of the underlying irregular surface. Remnants of the Fluvio-Volcanic Series now occur mainly along primary and secondary watersheds as narrow scarped plateaus or rows and groups of flat-topped and pyramidal hills.

One result of the elevation of the plateau and of the renewal of erosion was the freer circulation of the oxygenated waters through the earthy mantle and the consequent abundant precipitation of iron oxide as the level of the ground water gradually fell. With this is to be correlated the deeper staining and the greater content in iron of the upper portion of those relics of the Fluvio-Volcanic Series which still survive. The caps of lateritic ironstone, which are characteristic of the residual hills, and which have been largely instrumental in their preservation, represent certain portions of the original surface of elevation or of a later degradation level which were marked by the excessive deposition of iron in the subsoil. To this result many causes may have contributed, such as the local enrichment in iron of the ground water, the influence of bacteria in the soil, and of capillarity and

evaporation during the dry season, as well as the local issue of ferruginous springs on gentle slopes and valley floors. To the last is probably due the formation of the laminated clay ironstone, which sometimes occurs on the summits of the hills, and in which impressions of leaves are occasionally found. Often the ferruginous cap is simply brecciated ironstone, composed of the re-cemented detritus of some earlier ferruginous deposit which formerly existed in the vicinity. Those ironstone caps which exhibit a porous vesicular, and sometimes pisolitic habit are the enriched and hardened detrital surfaces of the red and white mottled grits and volcanic earths which so frequently

KWI HILL: A RELIC OF THE FLUVIO-VOLCANIC SERIES ON A BASEMENT OF OLDER GRANITE.

form the subsoil. The original mottling is due in part to the irregular deposition of iron, in part to the reducing action of decaying rootlets in the subsoil. On exposure the uncemented material is washed out, and the iron rearranged and compacted by local solution and redeposition and enriched by further capillary activity to form the characteristic scoriaceous cap. Where the deposition of iron is accompanied by that of alumina, the resulting cap may approach a true secondary laterite in composition.

The main economic interest of the Fluvio-Volcanic Series lies in the fact that the component grits, earths, and clays have covered up an old land surface, and with it the alluvial and the detrital tin-bearing deposits which had formerly accumulated along the river lines and on the valley slopes. It follows that underneath the existing remnants of the Fluvio-Volcanic Series there may occur buried river channels or detrital deposits rich in ore. As an example may be cited the occurrence of tin-bearing wash in Kwi Hill, a flat-topped pyramidal hill situated to the south of Kuru. The hill is composed of a thick (100 ft.) bed of volcanic earth or clay, representing a decomposed basaltic lava, set on a basement of gneissose granite with large parallel porphyritic felspars. The clay is white, yellow, or purple in colour, often striated at various angles, becoming vesicular towards the top, and covered with

HEAD OF A RECENT TRIBUTARY CREEK OF THE WERRAM RIVER, WITH A RELIC OF THE FLUVIO-VOLCANIC SERIES ON THE WATERSHED IN THE BACKGROUND.

a gritty ferruginous cap, underneath which the clay is veined, streaked, and knotted with iron ore. Beneath the volcanic earth is a gritty kaolin clay, which on the northern front overlies a deposit of tin-bearing wash much cemented with iron. This deposit had an extension of about 80 ft. into the hill, beyond which it became unpayable.

The Fluvio-Volcanic Series is thus worthy of careful prospecting for buried alluvial and detrital deposits. Its remnants can frequently be recognized as flat-topped hills or narrow plateaus, provided with caps of gritty lateritic ironstone. Where, however, the removal of the Series has been almost completed, relics of the same may be found

on secondary watersheds where no flat-topped hills occur to mark the spot. In their place may be simply rounded ridges or gentle slopes on which the base of the Fluvio-Volcanic Series is represented by a thin cover of sandy wash and broken ironstone.

Recent Volcanic Rocks.—During the period of erosion which followed the elevation of the plateau the ancient surface was largely destroyed and the present topography gradually evolved. The drainage system was rearranged, the present river valleys developed, and the tinstone content of the earlier superficial accumulations reconcentrated along the existing stream lines. This period of erosion was not, however, entirely continuous, one of the most important interruptions being caused by the renewed outbreak of volcanic activity on the surface of the plateau, with the result that large areas were flooded with basaltic lava. The lava not only covered up considerable tracts of country, from which the Fluvio-Volcanic Series had been entirely removed, diverting the rivers and streams from their established channels and burying the recent irregular surface of erosion, but it also mantled considerable areas from which the Fluvio-Volcanic Series had been only partially removed, with the result that it is now found in places wrapping round the bases of residual flat-topped and rounded hills, and in others capping the relic plateaus and adhering to the scarped slopes over which it flowed. It follows that underneath the recent basalts there are buried river valleys and stream channels of varying age, doubtless in some cases carrying rich deposits of tin-bearing wash.

Many foci, large and small, appear to have existed on the plateau, the smaller ones being of the nature of plugs from which little or no lava was emitted. The flows are always without porphyritic crystals of augite and olivine. Of the larger foci in the southern section of the areas mapped, one forms a prominent elevation on the principal watershed of the plateau to the south of the Ropp Hills. The lava of the focus is in places very vesicular and encloses numerous fragments of granite and gneiss. The adjoining flow has not only covered up and protected a considerable area of the Fluvio-Volcanic Series on the watershed, but has also descended over the northern escarpment into the valley of the South Ropp River.

Columnar Basalt in the Dum River.

Another important foci is that of Kassa on the Ropp road, about half-way between Bukuru and Ropp. The focus itself consists of a small group of rounded hills, but the lava from it flooded the whole country between the Kassa River and Kwi Hill, and sent a long tongue eastward towards Lafon, and another westward into the valley of the Kuru River, where, owing to recent erosion, only scattered patches of basalt now remain.

The economic interest of the recent volcanic series lies in the fact that the lavas have covered up an ancient land surface with its river valleys and stream channels, and its remnants of earlier superficial accumulations, all of which may at times carry ancient leads of tin-bearing wash. Prospecting for such deposits is, however, naturally costly and difficult, and little progress can yet be recorded.

ALLUVIAL DEPOSITS.—The progressive degradation of the surface consequent upon the elevation of the plateau can be clearly traced in the varied alluvial deposits of the existing valleys in those regions where recent volcanic accumulations are absent. During the early stages in the dissection of the plateau edge many creeks and gorges must have existed, from which, for various reasons, the streams were diverted at a later date.

Where quartz leaders or mineralized rock-carrying tinstone outcrop at the surface, sharp angular tinstone is found everywhere in the surface wash. On the other hand, when through the progress of denudation ancient terraces have been entirely removed from the slopes of a valley or when older alluvial deposits on watersheds have again come within the cycle of erosion, the surface wash of the valley slopes may carry rounded tinstone in greater or less abundance. On the northern front of the plateau well worn particles of tinstone may be found on bare disintegrating granite surfaces, and in the angular wash at their base. With the tinstone are associated occasional water-worn pebbles of topaz and white quartz, all of which are relics of ancient alluvial deposits.

With the exception of the sharp angular tinstone, which is still being shed from local sources at the present day, the greater part of the tinstone of the plateau tinfields would appear to have been detached and disintegrated from the original veins and lodes and mineralized streaks in the granite and the older rocks at a very early period and to have had a long and complicated alluvial history, of which only some of the latest stages can be traced to-day. In the oldest recognizable deposits of the Fluvio-Volcanic Series, which are generally also the highest, the tinstone is already well rolled and water-worn, and there can be little doubt that these ancient high-level deposits have been the proximate source of the greater part of the tinstone now distributed throughout the lower alluvial accumulations.

The bulk of the tinstone of the plateau tinfields is black in colour, but ruby and grey tin are both common, the latter being sometimes almost white. Small quantities of wood tin are found in places. A semi-translucent resin tin occurs at Forum River, and a somewhat similar variety at Rafin Sainyi on the Ngel River. Black tinstone with a black streak, and in small particles attracted by the electromagnet, occurs near Amo. When in well-formed crystals the tinstone occurs mainly in short square prismatic forms, frequently showing the characteristic twinning. No pseudomorphs in tinstone after felspar or quartz have been definitely recognized. The minerals most commonly associated with the tinstone in the alluvial deposits are topaz, ilmenite, magnetite, rutile, zircon, monazite, garnet, and more rarely columbite, wolframite, corundum, and gold.

The alluvial deposits of the plateau tinfields, all of which in places carry tinstone, may be classified as follows :—

(1) Deposits unrelated to the present drainage system.

(*a*) Deposits of the Fluvio-Volcanic Series.

(*b*) Deposits preserved underneath recent lavas.

(2) Deposits related to the present drainage system.

(*a*) Low terrace deposits with bedrock on the same level as the present stream bed.

(*b*) High terrace deposits with bedrock above flood level of the present stream.

(*c*) Valley flat deposits with bedrock below the level of the present stream.

(*d*) Stream bed deposits in hollows and pockets of rocky channels.

(*e*) Eluvial or detrital deposits.

So varied are the types of stanniferous deposits upon the plateau, and so complex has been the history of the present surface, that almost every square yard deserves prospecting to bedrock. Rich alluvial deposits may occur not only in the present stream beds and banks, but also on the watersheds, on the valley slopes, in buried channels, and in ancient river beds, to which the present topography may afford no clue, while surfaces of bare rock may exhibit areas of primary alteration and mineralization, which, if unremunerative in themselves, may yet indicate the presence of valuable secondary deposits in the vicinity.

THE IRON AND STEEL INDUSTRY OF INDIA

By J. COGGIN BROWN, O.B.E., D.Sc., M.Inst.M.M., F.G.S.,

Officiating Superintendent, Geological Survey of India.

This article is written with the permission of the Director, Geological Survey of India.

Introduction.—In this article an attempt is made to give a connected account of the development of the iron and steel industry in India. The first part is mainly historical and deals with indigenous methods. It is followed by brief notices of the early attempts to introduce modern methods which have culminated in the successful enterprises of the present day; and then by a summary of our present knowledge regarding the iron ore resources of India and their relations to its coal reserves. A very extensive literature has grown around the subject, and the following notes are a compilation from the more important papers, published under official auspices and by private workers. It is hoped that such a review will help towards a better appreciation of the promising outlook for the future of the Indian iron and steel industry. The writer is indebted to the authors he has quoted, especially to those whose papers appear in the Records of the Geological Survey of India, and also to the Tata Iron & Steel Co., Ltd., and the Bengal Iron Co., Ltd., who have kindly revised the portions dealing with their works.

The approximate date of the introduction of iron into India, or of its first manufacture in the country, is not known. At the time of Alexander's invasion (326 B.C.) the armed nations of Northern India were as familiar with the use of iron and steel as the Greeks themselves. Quintus Curtius mentions that the chiefs of the Punjab presented Alexander with 100 talents of steel. Archæologists who have studied the prehistoric remains of Northern India believe that the Iron Age may well go back to 1500 or even 2000 B.C. there. The antiquity of the knowledge of iron metallurgy in India may be judged from the rusted implements found in the urn burials of an early period; from the famous pillar at the Kutab near Delhi; from the forged iron bars of the temples of Orissa; from the hammered door panels of ancient shrines and tombs; and from the superb collections of arms preserved by the princes and nobles. Burma is noted for the iron ornaments and balustrades of its pagodas, while the engraving and carving of iron and steel in such articles as armour, weapons, shields, and caskets has been carried on from time immemorial. The pillar at Delhi weighs over 6 tons, is of solid wrought iron of an excellent type, 23 ft. 8 in. in height, 16½ in. in diameter at its base, and 12 in. just below the capital. It is sunk into the ground for 20 in., and there expands into a bulbous form, 2 ft. 4 in. in diameter, resting on a grid of iron bars fastened with lead into a stone pavement. Incised on the pillar is a Sanscrit poem, constituting the epitaph of the Gupta king Chandragupta II, composed in or about A.D. 415. This iron pillar is not unique. There is another, in fragments, which was apparently nearly twice the height of the one just described, at Dhar in Central India. But while the Dhar column bears a Persian inscription of Akbar, incised in A.D. 1591–2, there is no original record on it, placed there when it was set up.

The manufacture of "wootz", or Indian steel, anticipated the cementation process by many centuries, and some authorities believe that it was exported to the west long before the Christian era. There seems little doubt that it was from Indian crucible-steel that the celebrated Damascus sword-blades were made, and these had long enjoyed their reputation for flexibility, strength, and beauty before it was recognized that the alloy from which they were fashioned was produced in obscure Indian villages, whence it was obtained by Persian traders.

Further information on this subject will be found in the *Imperial Gazetteer of India*, vol. ii, pp. 25 and 98; and in *The Commercial Products of India*, by Sir George Watt, p. 692.

The Indigenous Industry.—For information under this heading reference may be made to the following publications:—

6 N[illegible] papers in the [illegible]

Until it almost succumbed in comparatively recent times under the competition of imported metal, the indigenous Indian iron industry was both widespread and prosperous, capable of meeting all the internal demands of the country. There is hardly a single district in India from the extreme south to the Himalayas, or from Baluchistan to the Shan States of Burma, with the exception of the great alluvial plains of the Indus, Ganges, Brahmaputra, and Irrawaddy, where heaps of old iron slags have not been found. Iron ores of high enough grade and in large enough quantities to meet the small requirements of the primitive smelter occur in most of the geological groups, though it by no means follows that all of them are worth consideration from the modern point of view.

Quartz schists carrying magnetite and hematite are very prevalent among the crystalline rocks of peninsular India. In the Vindhyan formations iron compounds are disseminated through immense thicknesses of beds giving rise to the red and brown tints characterizing these rocks.

The ironstone shales of the Gondwana system, in the Damuda Valley, take their name from the limonitic and sideritic ores they contain. Other divisions of the same system elsewhere carry segregations and thin bands of iron ore, utilized in the past by the native smelters. The nodules of ironstone which occur in the Cretaceous rocks of the Trichinopoly district were at one time collected and smelted by the local inhabitants. The rivers draining the Deccan Trap not infrequently deposit magnetite sands derived from these basic rocks. Ferruginous laterites are exceedingly common and their basal layers often form easily worked brown hematites. Such ores have been reduced on a small scale over the whole of India. The Indian smelters in the Himalayan region found their ores in both the Tertiary and the crystalline rocks. On the Shan plateau of Upper Burma residual iron ores occur in the red earth which forms a mantle over a great part of the country, and as gossans to certain veins. But the only deposits which have proved large enough for the requirements of the modern blast-furnace are those of the peninsular Dharwar rocks, though the concretions from the ironstone shales of the Raniganj coalfield were used for some years before being finally abandoned. The ancestral Indian iron-maker, however, drew his supplies from any of the formations mentioned, breaking up the quartz-iron ore schists and concentrating his product by winnowing it in the wind, or washing it in a stream; picking out the richer bits from the ferruginous laterites, or the rusty cement from the ancient sandstones; or panning the sands of the river beds. The Khasias, a hill tribe in Assam, used to obtain their iron ore by the systematic ground sluicing of decomposed granite and gneiss.

In spite of the competition of imported iron goods and of the gradual diminution of the available charcoal fuel, the manufacture of iron by the old, small-scale method still persists in isolated parts of India. In 1913 there were furnaces working in a few districts of Bihar and Orissa, the Santal Parganas, Monghyr and Sambalpur; in the Kumaun Himalayas; in Mysore; in the districts of Malabar, Salem, and Trichinopoly of Madras; in Hyderabad; and in some of the States of Central India. The industry shows signs of greater activity in the Central Provinces than elsewhere, but even there signs of an approaching end are apparent. In 1909 there were 510 small Indian blast-furnaces in operation, but by 1919 the number had fallen to 159. The average annual production of iron for the five years ending 1909 was 557 tons for the whole of the Central Provinces, but no returns are available for later periods.

The principles of iron smelting as carried out by the natives of India are practically the same in all parts of the country, though the dimensions of the furnace and the construction of the blast-producing apparatus vary from place to place. Descriptions of the furnaces have been given by many writers, including Dr. Percy in his *Metallurgy of Iron and Steel* (1864). A useful bibliography has been compiled by Sir Robert Hadfield which brings the list of references to comparatively recent times (see *Journ. Iron and Steel Inst.*, vol. lxxv, 1912, pp. 170–2). The latest paper on the subject is one by Dr. A. McWilliam, who gives an account of aboriginal methods which are still being carried on almost under the shadow of the Tata Iron & Steel Works (see *Journ. Iron and Steel Inst.*, vol. cii, 1920, pp. 160–70).

In the early part of the eighteenth century the industry attained a comparatively high stage of development in the western parts of the Birbhum district of Bengal. The furnaces

are stated by contemporary writers to have been capable of turning out about 35 tons of iron per annum each, which, contrary to the usual practice, was tapped in a molten condition and then refined by a second process resembling puddling. In Malabar, too, at a later period, furnaces up to 10 ft. in height were common. Built from a mixture of red clay and sand, and held together in a stout wooden frame, they were fitted with two platforms in front to support the four goat-skin bellows arranged in pairs, and at the back with a pit into which the molten slag trickled from a slag-hole. In this type a bloom of iron weighing about 5 cwt. was produced in from 48 to 60 hours.

As a general rule, however, the furnaces are much smaller than these, heights of 3 or 4 ft. being common. They are built of clay or of sun-dried bricks, and are conical in form. In front, near the bottom, there is an opening which is stopped with clay while the blast is on, and through which the bloom is removed at the end of the operation. Clay tuyeres are inserted near the base and convey the blast from two skin or leather bellows, worked alternately to keep up a continuous stream of air. A few variations from this general type may be briefly mentioned. Thus the furnace of the Narsinghpur district of the Central Provinces was built across the centre of an oblong pit dug in the ground. Its hearth was made of stone work, and the blast, from bellows of concertina form, was conducted through iron pipes. It is recorded that a suspension bridge was built in 1830 across the

Bias River from iron which had been produced in furnaces at Tendukheda in this district. The Manipur furnaces had their tuyeres inserted at the back, while in front, and opposite to them, was a semicircular opening some 9 in. across through which the products of combustion passed. The upper part of the furnace was only used for feeding in the ore. Remains of furnaces have been found in Upper Burma in banks of firm alluvial clay. They appear to have been used in making iron without the aid of an artificial blast. In Kathiawar the furnaces were of a very unusual shape, being rectangular in section and constructed of brickwork lined with clay. A chimney was built into one end, and close to the opposite extremity were two holes. Through one of these the blast entered, and by the other the slag was removed. A few workers still remain in the isolated parts of the Himalaya Mountains, but their " bloomeries " are much the same as those of the plains. The bellows differed vastly in size and shape in various parts of the country, but were nearly always made of goat or bullock skins, worked either by the hands or by the feet. Indians do not seem to have evolved a mechanical blower such as that used by the ancestral Chinese in their metallurgical operations.

As a rule, only the softer varieties of ore are smelted, and it is the custom to clean and concentrate them before they go to the furnace. The fuel employed is charcoal, and, with the exception of the Waziris who utilized nummulitic limestone for the purpose, no flux is used. When the furnace has been brought to a sufficiently high temperature the ore is sprinkled in at the top, in small quantities at frequent intervals, and alternately with sufficient charcoal to keep the furnace nearly full. From time to time during the blast, which lasts several hours, the slag is removed through a hole which is then plugged up again. At the end of the operation the blast is stopped, the front orifice opened, and the bloom removed. It is refined by re-heating and hammering, often repeated more than once, as the temperature is seldom high enough to cause the liquefaction of the charge. Sometimes the refining is done by the smelters, but more usually they cut the bloom almost in two halves, to display the quality of the metal to the buyer, and sell it in that state, when the further purification is carried out by others. The consumption of charcoal in the Indian process is very high in proportion to the amount of iron obtained, but the metal, by reason of its purity and malleability, has always been held in great esteem by Indian blacksmiths, who use it for the manufacture of all kinds of agricultural and domestic implements such as spades, hoes, ploughshares, sickles, hooks, axes, spoons, and pans. For these purposes it is preferred to foreign-made iron, when it can be obtained readily. At some localities in the Jubbulpore district of the Central Provinces a manganiferous hematite is smelted and a steely iron known as " kheri " made. This is in demand in the surrounding regions, and is welded by the blacksmiths on to the ordinary country-made soft iron to form the edges of knives, scythes, and ploughshares, the striking faces of hammers, and the heads of anvils.

The " lohar " or " agaria ", as the native smelter is called, belongs to the lowest ranks of the proletariat, and although the metal which he makes is sold at a comparatively high price, the bulk of the profit is said to go to the traders through whose hands it passes. On the whole his processess are very inefficient, and the iron turned out bears but a poor relation to the material, labour, and time expended. The " lohar " flourishes longest in the most inaccessible parts of the country, where there is an abundance of timber and an absence of restrictions against its destruction, and where there are difficulties in the way of distributing European iron and steel. Yet the readiness with which foreign articles are obtainable even in the remotest bazaars, and the tempting wages which may be earned elsewhere, owing to the general industrial progress of the country, combine to encourage the iron-makers to desert their hereditary occupation.

Indian Crucible Steel.—Steel is made by the inhabitants of South India either by the carburization of wrought iron in crucibles, or by the decarburization of cast iron. The former product alone is the true " wootz ". The following descriptions of the two processes have been given by Sir T. H. Holland. In the Trichinopoly district the crucibles are made of a mixture of ferruginous clay with charred rice-husk and are about 6 in. in height and 3 in. in diameter. They are charged with pieces of wrought iron, together with 4 or 5% of its weight of wood of the " Avaram " tree (a species of *Cassia*), and with leaves of certain shrubs, and then tightly sealed with clay. Twenty-five crucibles are built up into an arch in a furnace fitted with a tuyere connected to a bellows. After about two hours continuous blast the twelve central

crucibles are removed, having been subjected to a greater heat than those around the sides. By this time the iron is well fused and carburized. The crucibles which are taken out are replaced by fresh ones, previously raised to a high temperature by having been placed on the surface of the arch during the blast, and the process is continued. The charcoal fuel is fed in from below. The finished ingot retains the shape of the bottom of the crucible.

In the Salem district, during the manufacture of wrought iron, certain easily fusible beads of iron are produced and melted off as shot. These are in reality highly carburized particles, or cast iron, and it is from them that the steel is made. A hole is dug in the ground about one foot deep and one foot in diameter. At one side a semicircular groove is cut from the surface to the bottom of the pit. This is separated from the rest of the excavation by a clay partition. The bottom of the small chamber is covered with a layer of quartz. On this an ignited coal is placed and the chamber filled with charcoal. A tuyere, built in with the partition, points downwards and receives the blast from two bellows. The cleaned shot are thrown upon the charcoal and the blast continued for about half an hour, when the process of decarburization is complete, and the tuyere and clay partition are broken down for the removal of the steel cake, which is cooled by sprinkling water on to it and hammered to remove its casing of slag.

Early European Methods.—Failure attended every early attempt to graft European methods on to the native processes and to manufacture iron on a large scale in India. About the year 1825 Mr. J. M. Heath, formerly of the Madras Civil Service, obtained from the directors of the East India Company an exclusive right to manufacture iron on a large scale in that Presidency. In 1830 works were established at Porto Novo in the South Arcot district, with the aid of advances from the Government, and in 1833 the business was taken over by a Company, the works were enlarged, and a new plant established at Beypore on the Malabar Coast. Free mining leases and fuel cutting rights were granted, but in spite of these privileges the undertaking failed. Pig iron made at these works was sent to England and commanded a good price for conversion into steel. A large quantity of it is said to have been used in the construction of the Britannia tubular and Menai suspension bridges. In 1853 a new association, the East India Iron Company, was started. It also held exclusive mining rights over several districts in Madras and erected blast-furnaces at Trinomalai in South Arcot and at Pulampatti in the Coimbatore district. Operations ceased at Porto Novo in 1866, and at Beypore and Trinomalai in 1867.

The history of the attempts made to manufacture iron on a large scale in Bengal is a long one, dating back to the year 1777, when Messrs. Motte & Farquhar applied for the exclusive privilege of smelting iron, and of selling the metal free of duty over a large portion of the province. On their part they contracted to supply shot and shell to the East India Company at Fort William, at four-fifths of the average cost of the same when landed from Europe. In 1779 Mr. Farquhar obtained an advance from the Government to enable him to complete his furnaces, but by 1789 he had relinquished the speculation.

In 1852 Dr. Thomas Oldham, the first Director of the Geological Survey of India, reported on the iron ores of Birbhum and the Damuda valley. The court of directors of the East India Company had especially directed his attention to the question of iron manufacture in connexion with the introduction of railways into India. At this time about seventy native furnaces were at work in Birbhum alone. About the year 1855 Messrs. Mackey & Co., of Calcutta, erected iron furnaces at Mahomed Bazaar in Birbhum and made small quantities of pig iron of superior quality for a number of years before closing down. A final experiment started by Messrs. Burn & Co. in 1875 was soon abandoned. The Kumaun iron works at Kaladhungi in the foothills of the Himalayas, in the United Provinces, commenced operations in 1857, and, after many vicissitudes, failed like all the earlier ventures. Another attempt was made about 1862 at Barwai in Indore, a State of Central India. A Swedish specialist was engaged by Government, a blast-furnace, rolling mill, and charcoal ovens were nearly erected, and a large quantity of ore proved, when Government abandoned the enterprise. The Raja of Sirmur, a State in the Punjab Himalayas, had a blast-furnace and a foundry built in 1867, designed for an out-turn of 75 tons per week. History is silent regarding the progress of the undertaking, but some time later the foundry was converted into a sugar-cane mill!

For all these schemes charcoal was the fuel used, or proposed to be used, and it was not until 1875 that advantage was taken of the

Indian coal supplies. In that year two large-scale experiments were made at Warora, in the Central Provinces, in smelting rich ore from the Chanda district with the local coal. (In 1839 Messrs. Jessop & Co., of Calcutta, had attempted to smelt Burdwan ore with coke on a very small scale, but the results were inconclusive ; see V. Ball, p. 390.) The results may be described in an observer's words : "The hearth quickly filled with spongy iron which would not liquefy. The blast was intensified and more blank charges of coal added. The temperature in the hearth increased, and the fire-bricks, the tymp plate, and even the bottom of the hearth, were fused ; still the iron that had settled down was so mixed with the ashes of the coal that it would not liquefy, and only kept accumulating till the iron reached the top of the tuyeres, and then a stop was put to all further proceedings till the mass was dug out, which was over a ton in weight." So ended the first attempt to smelt Indian iron ore with Indian coal.

The Barakar Iron Works Co. was formed in 1874. Two furnaces were erected at Kulti near Barakar, each capable of producing 20 tons of pig iron per day. The ores were clay ironstones obtained fron the surface in the neighbourhood of the works. The limestone flux was quarried from crystalline rocks a short distance away, and the principal fuel used was coke made from coal either from the Karharbari field or from mines of the Raniganj field within a few miles radius of the works. The company came to an end in 1879 after producing some 13,000 tons of pig iron. The chief reason for its failure is believed to have been insufficiency of capital. In 1882 the concern was taken over by the Government, and the first blast-furnace was restarted in 1884. In 1889 the works were resold by the Government to the Bengal Iron & Steel Co., who entirely remodelled and gradually developed them, until, with four blast-furnaces, they have to-day a potential output of 10,000 tons of pig iron and 1,500 tons of ferro-manganese per month. The Bengal Iron & Steel Co. completed the erection of a steel plant at Kulti in 1903. The Siemens Martin basic open-hearth furnaces had a capacity of 20,000 tons of steel per annum. The experiment, however, was not successful, and the plant was closed down before 1905. In 1919 the company was reconstituted as the Bengal Iron Co., Ltd.

The successful operations of the Bengal Iron & Steel Co., Ltd., in the later stages of its career under that constitution, mark the establishment of modern iron metallurgy in the Indian Empire on permanent foundations, and the next step in building up the industry was the inauguration of the Tata Iron & Steel Co., Ltd.

INDIAN IRON AND STEEL TRADE. Before considering its rise and development it is advisable to glance for a moment at the iron and steel trade in India generally. In 1912, the year in which the blast-furnaces of the Tata Company were completed, India's domestic production of iron amounted to about 50,000 tons per annum, while her requirements of iron and steel may be gauged from the imports in the same year, which totalled upwards of 700,000 tons covering a great diversity of products. In the last twenty years there has been a very remarkable increase in the consumption of iron and steel in India, though the import trade suffered a general set-back during the war. The above table gives the quantity and value of the heavy iron and steel imports for the fiscal years ending March 31 in 1912, 1914, and 1920.

In this table manufactured iron includes angles, rods, bars, channels, and bolts. The steel manufactures include similar products, together with ingots, blooms, billets, and cast steel in addition. The undifferentiated iron and steel articles comprise beams, pillars, girders, hoops, strips, rails, chairs, sheets, plates, wire, nails, rivets, etc. A consideration of similar statistics for the quinquennial period 1913–18, in which allowances are made for the domestic production, for exports and re-exports, leads to the conclusion that India's consumption, during a series of years in which her industrial development was retarded by the war, was in the neighbourhood of one million tons per

annum. There is every reason to believe that this figure will show a rapid rate of increase in the future.

Yet the articles which have just been enumerated by no means represent India's total imports of iron and steel goods, and to gain a more accurate appreciation of the true position, the more highly finished articles such as machinery, railway plant and rolling stock, hardware and cutlery, have to be taken into account. Adding the values of these to the values of the heavy goods of the above table, the totals become as follows :—

Years.	Total Value of Iron and Steel Materials. Approximately.
1912	£16,000,000
1914	£27,000,000
1920	£25,000,000

The manufacture and rolling of Indian steel was successfully established about the end of 1913, after the usual preliminary difficulties, always met with in the introduction of complex metallurgical processes into new countries, had been overcome. Before the war Indian pig iron had been shipped to Burma, the Straits Settlements, Ceylon, Java, Manchuria, China, Japan, Australia, New Zealand, the United States, and South America. During the war export was prohibited, and the whole output of Indian rails from the Tata works was taken by Government for military purposes in Mesopotamia, East Africa, and Palestine, a portion being even shipped as far as Salonica. Shell steel was supplied to the Indian munition works, and both the Tata works and the Bengal Iron Co. made ferro-manganese on a large scale.

THE TATA IRON & STEEL CO., LTD.—Jamsetji Nusservanji Tata, a member of the priestly caste of the Parsees, who was born in the State of Baroda in 1839, was the first Indian to realize the possibilities of an extensive iron and steel industry in his native land, and he also possessed the foresight to visualize the potential developments which have since come to pass. The operations of the Bengal Iron & Steel Co., Ltd., had already proved beyond question that pig iron could be made profitably in India, and it remained for Mr. Tata to institute the second iron-manufacturing concern and to introduce modern steel works and rolling mills.

The Tata Iron & Steel Co., Ltd., was formed in 1907 with a capital of Rs. 2,31,75,000 (£1,545,000). To-day it has an authorized capital of Rs. 10,52,12,500 (£7,014,166), of which Rs. 3,98,04,570 are issued. After preliminary investigations in India, Europe, and America, Mr. Tata engaged Mr. C. P. Perin, of New York, as his consulting engineer. The latter's associate, Mr. C. M. Weld, arrived in India in 1902, and for some years examined various iron ore deposits, many of which had been discovered in the first instance by the officers of the Geological Survey of India. The earlier work was carried out in the Central Provinces, and large reserves of excellent ore were proved, but the forest resources of that region did not prove big enough to warrant the establishment of a charcoal iron works there. The surveys were then continued further on towards the east, in order to approach the coalfields of Bengal more closely, and finally the deposits of Gurumaishini in Mayurbhanj were chosen as the source of the iron ores.

The works are situated at Jamshedpur (formerly known as Sakchi), adjoining Kalimati station on the Bengal-Nagpur Railway. This place is 154 miles west of Calcutta, about 115 miles from the Jherria coal mines, 100 miles from the limestone quarries, and 45 miles from the Gurumaishini iron ore mines. The following description of the Tata works is compiled from papers by Messrs. Perin, Tutwiler, and Surtees Tuckwell. The writer is especially indebted to the last-named for his kind assistance. Construction commenced in 1908, and the Sakchi jungle was rapidly transformed into a town, which now promises to become the centre of one of the leading industrial regions of Asia.

The two original blast-furnaces of the company, each 77 ft. high and 19 ft. in diameter, with a capacity of 200 tons of pig iron per day, were blown-in in November, 1911, and September, 1912, respectively. Each furnace is equipped with up-to-date charging apparatus and four Cooper-Kennedy stoves. These two furnaces have since been enlarged to turn out 280 tons per day each. The shortage of ferro-manganese in India during the war led to the rapid erection of a third furnace of a somewhat smaller type in 1919. At the present time two of the most modern skip-filled furnaces, with a capacity of 600 tons per day each, are nearing completion.

The original coke-oven plant consisted of 180 Coppée non-recovery ovens. To these have been added a battery of fifty Koppers by-product ovens and a Simon Carves

sulphuric acid plant, which supplies the acid necessary for the production of sulphate of ammonia. Three batteries of Wilputte design, each containing fifty ovens, are being added, together with extensions to the coal tar, ammonium sulphate, and benzol recovery plants. All the silica shapes requisite for the construction of these new ovens have been made in India by the Kumardhubi Brick Co.

The steel works plant consists of one 300 ton mixer, which receives the molten pig iron from the blast-furnaces before it is charged into the open-hearth furnaces. There are seven of the latter, four of which have a capacity of about 55 tons per heat and three of 75 tons capacity. These enable an output of 27,000 tons a month to be maintained. The new steel plant includes two 25 ton Bessemer converters, two 100 ton tilting open-hearth furnaces, and one 1,300 ton mixer. The converters will remove all the silicon and as much carbon as is desired from the iron, leaving the tilting furnace the duty of removing the phosphorus and sulphur and bringing the iron to the required percentage of carbon. The elimination of these elements is said to reduce the time necessary for the finishing of a heat in the tilting furnace by about 75%. The large mixer is being erected to store the hot metal from the blast-furnaces over the week-ends, when the open-hearth plant is not working. The present 300 ton mixer is to be used as an additional open-hearth furnace after the new mixer is built. Provision has also been made for the installation of a 250 ton recarburizing mixer, a third converter if necessary, a third duplex tilting open-hearth furnace, and three Heroult electric furnaces for the manufacture of special steels or ferro-alloys.

There are four soaking pits in the steel works, equipped with mechanically operated lids, and an electric overhead charging and drawing crane. The ingots are made 21 in. by 19 in., and weigh between 2 and 3 tons each. They are removed by a self-tipping electric trolley to the mill tables.

The blooming mill consists of a 40 in. mill, operated by a Galloway engine of 11,000 h.p. In this mill the ingots from the soaking pits are made into blooms and billets. Another 40 in. reversing motor-driven blooming mill with hydraulic manipulator and followed by hydraulic shears is being added.

The present 28 in. finishing mill has three sets of rolls, and is worked by a 12,000 h.p. engine. It is capable of turning out rails from 100 lb. to 30 lb.; beams from 15 in. by 6 in. down to 5 in. by 3 in.; angles from 6 in. by 6 in. to 3 in. by 3 in.; and channels from 12 in. by 4 in. to 6 in. by 3 in. The blooms from the blooming mill are reheated before they are rolled, and the sections of rails or structural materials, after being rolled to the required dimensions, are cut by circular saws into the necessary lengths, and are conveyed mechanically by rollers to a cooling bed of the moving type. From the cooling bed all the bars and rails are passed through straightening machines in the finishing department, which also contains the usual planing and drilling devices. The products are handled by an overhead electric crane. The motor-driven blooming mill will serve a new 28 in. to 30 in. combination rail and structural mill.

There is one 16 in. bar mill making light rails weighing 30 lb. to 14 lb. to the yard; angles of all sizes from 3 in. to $1\frac{1}{2}$ in.; channels from 4 in. to $1\frac{1}{2}$ in.; beams of 4 in. by $1\frac{3}{4}$ in.; and fish-plates for rails. There are also two 10 in. mills devoted to the production of lighter sizes of flats, squares, and rounds. The new bar mill is of the latest continuous type, and will take billets from the sheet, bar, and billet mill at present under erection. Independent motor-driven rolls are being added for the production of wire rods.

The plate mill is now nearly completed in a separate building over 1,000 ft. long and about 100 ft. wide. The mill will produce plates from $\frac{1}{8}$ in. to $1\frac{1}{4}$ in. thick in various widths up to 96 in. and various lengths up to 50 ft. It is to be driven by a 2,000 h.p. motor taking alternating current at 3,000 volts, and is provided with four bottom-type reheating furnaces. The building also contains the straightening and shearing machines for the plates.

The sheet, bar, and billet mill is in direct line with the new blooming mill, and will roll billets from $1\frac{3}{4}$ in. square to $6\frac{1}{2}$ in. square for the bar mills. It will also roll sheet bars up to 8 in. wide for the sheet mill. It is proposed to finish steel sleeper sections up to 16 in. wide on this mill.

The sheet bars will be delivered from the mill just described to the sheet mill proper, where six special furnaces will reheat them. The rolling equipment consists of two jump rolls, two balanced rolls, six finishing mills, and two cold rolling mills,

all driven by a 4,000 h.p. motor taking alternating current at 3,000 volts. This mill will produce sheets to any width up to 38 in., and of any thickness desired from ⅛ in. down to 0·01 in.

The present scheme of extensions also contemplates a wire mill capable of producing 20 tons of miscellaneous sizes of wire per day of 24 working hours, to be used for fencing, wire-netting, nails, etc. ; a bolt and nut shop with a sufficient number of machines to produce 50 tons per week ; a steel sleeper press ; a cast-iron pipe foundry ; and a new roll-turning shop. A large new machine-shop is under erection, in which the housings, castings, and the bulk of the heavy components for the new rolling mills, etc., are now being made. In addition there are shops for pattern-makers, carpenters, blacksmiths, locomotive repairs, electrical repairs, and structural shops for bridges, roofs, and buildings.

The power-house contains three turbo-blowers, which supply 32,000 cubic feet per minute to the blast-furnaces under a pressure of 15·5 lb. per square inch. The plant consists of two 1,000 kilowatt and one 1,500 kilowatt, 3,000 volt turbo-alternators, running at a speed of 3,000 revolutions per minute, and three transformers of 1,250 K.V.A., 3,000 to 440 volts, and two motor generator sets of 500 kilowatts each.

To supply the power for the new extensions, the whole of which will come into operation progressively within the next two years, large additions to the former power-plant have been necessary. These include a large range of new boilers, fired with blast-furnace gas, three 5,000 kilowatt turbo-generators, one 4,200 kilowatt turbo-generator, one 2,000 kilowatt generator, one 2,000 kilowatt mixed pressure turbine, the steam for which is principally obtained from the existing rolling mill engines, and the necessary transforming equipment to step down from high to low tension. Corresponding increases have been arranged in the water system, pumping plant, the transporting department, laboratory, offices, etc., to say nothing of the essential augmented reserves of raw material.

When the present extensions are completed, the Tata iron and steel works will have a potential output of 700,000 tons of pig iron and 580,000 tons of steel ingots per annum. Of the latter, it is proposed to convert some 426,000 tons into finished and semi-finished products, and the whole of the new plant has been so laid out that future extensions may be added with the least inconvenience.

The company owns its own collieries, iron ore mines, manganese ore mines, wolfram mines, and limestone and magnesite quarries. It also holds a large interest in the Kumardhubi Silica & Fire Brick Co., Ltd., which makes silica bricks from the gannister deposits of the Gaya region, magnesia products from Mysore magnesite, and other refractories from fire-clay, chromite, etc. The Tata Company to-day finds employment for 25,000 men and women, and, as it is still the custom of the ignorant to underestimate the capability of the Indian workman, it may be pointed out that the management has gradually been able to reduce the number of European and American employees and to substitute Indian labour. For example, in the bar mill, three eight-hour shifts, which would necessitate the employment of twenty-seven Europeans, are manned by a crew of twenty-five Indians, who run the plant economically with only two European superintendents. In other departments similar reductions have been made. Out of 137 covenanted Europeans and Americans, 75 are employed as supervisors at the steel furnaces and rolling mills, which between them find employment for 4,200 men. At the blast-furnaces there are only 8 Europeans to 1,600 Indians ; in the mechanical department 6 to 3,000 ; and in the traffic department only 1 to 1,500. The chemical laboratory originally employed five European chemists. Now the chief and the assistant are Europeans, the remainder of the staff being twenty-one Indians. According to Mr. H. Surtees Tuckwell, " in very many instances Indian workmen have shown themselves possessed of extraordinary skill and manual dexterity, and the electrical department is under the superintendence of an Indian gentleman, a graduate of an Indian University, assisted by a staff of Indian wiremen and electricians." The coke-oven department is also under the sole charge of an Indian. Social welfare work among the employees is actively undertaken at Jamshedpur, which is a well-laid-out town possessing a modern water supply and sanitation system, hospitals, schools, and recreation grounds.

(*To be concluded.*)

BOOK REVIEWS

Recent Practice in the Use of Self-contained Breathing Apparatus. By Lieutenant Rex C. Smart. Cloth, octavo, 310 pages, illustrated. Price 15s. net. London: Charles Griffin & Co., Ltd.

The title does not fully indicate the character of this valuable work, for the book goes far towards being a textbook on mine rescue organization and the training of men in the use of breathing apparatus. As officer in charge of the First Army Mine Rescue Station, B.E.F., the author had exceptional opportunities for the study of mine rescue work under the severe conditions of military warfare. His record of experiences in the employment of breathing apparatus should be of general interest to mining engineers and of considerable value to those connected with rescue stations. The subject is treated from a military standpoint, but though there are such references as " Pails Mark I and II ", " as per A.F. W. 3419 ", and " the O. i/C. School ", the book generally is free from military jargon, and civilian readers will have no difficulty in following the text.

It was essential that appliances on any portion of the army front should be standardized as far as possible. The author gives brief notes on leading types of rescue appliances, but the only appliances dealt with in detail in this work are of the Proto, Salvos, and Novita designs.

The account given of the course of training for tunnellers of the Royal Engineers at the Mines Rescue School in 1916–17 suggests that the holder of a certificate of competency from that training centre would be able to do work equal to that of the most efficient members of English colliery brigades at the present time. Lieutenant Smart gives full details of the tests for proficiency and the examinations at the schools, and the questions may be studied with advantage by any member of a mine rescue team. As illustrating the searching character of the examination, we may say that there are given 16 questions on the rubber bag and its contents in dealing with the Proto apparatus, and under the heading of pressure gauge valve 21 questions might be submitted to a candidate.

Points to be observed in adjusting the apparatus and notes on repairs form a valuable feature of the publication, and the tables of statistics relating to stocks and parts of apparatus repaired, as illustrations of efficiency in organization, should be of service to those who have to arrange the office routine of a rescue station on a large scale.

The section on the charging and testing of apparatus is well written, but the illustrations of oxygen cylinders are not so clear as is desirable. A system of air and water circulation is generally better shown by plain line diagrams, such as the author employs for illustrating the design of valves, than by reproductions of photographs of assembled fittings.

Physiological considerations connected with the use of respiratory apparatus are dealt with in an able manner, but in several instances expressions might be modified to the advantage of the general reader who would probably understand references to heart-failure and difficulty in breathing more quickly than he grasps the purport of the statement that " men may suffer from oxygen deficiency syncope without dyspnœa symptoms ".

Considerable attention is given to the phenomena of gas explosions. The effects of explosions in collieries are generally complicated by the presence of finely divided coal. There was no possibility of inflammable dust being present in the galleries on the army front, where gas explosions occurred, and data on effects of force and other features are worthy of record for comparative purposes in the study of explosions underground.

Methane or firedamp (CH_4) may be one of the products of the detonation of nitrocellulose, but the most dangerous gas derived from gun-cotton, ammonal, and other explosives used in military mining was carbon monoxide. After the explosion of a charge, which frequently amounted to many tons of explosive, the enclosing strata were likely to be saturated with noxious gases. The effect was particularly noticeable with " camouflets ", that is, where the charge of explosive was not sufficient to break through to the surface of the ground, no mine crater being formed. The gases occluded in the rocks discharged themselves into the galleries, which stood open after the mine was fired, and secondary explosions resulted in many instances from the ignition of gases by candles. Plans are given showing areas of workings affected by explosions of this type. They appear to be very local in character, although in some cases considerable force was developed. The author

notes occasions where a succession of explosions occurred at regular intervals of two or three minutes duration.

In dealing with the features of carbon monoxide poisoning it is stated on the authority of Marshall, p. 577, that miners' phthisis was due principally to carbon monoxide poisoning in the South African gold mines. This is not in accordance with the views of leading authorities on miners' phthisis, a matter which has received considerable attention from those connected with the gold-mining industry. Inhalation of noxious gases may have influence on the resistant power of the lungs, but the presence of fine silicious dust in the atmosphere is almost universally regarded as the primary if not the sole cause of miners' phthisis on the Rand.

As the equipment of a mine rescue station is not complete without a supply of small creatures for testing the purity of air, Lieutenant Smart gives notes on the care of mice and canaries in the concluding section of his work. We learn that oxymel of squills may be given with advantage to birds suffering from bronchitis, and what is a good design of cage for the housing of mice. As a sidelight on the thorough nature of military organization, we learn from another portion of the book that mice may be regarded as units on the strength of a company, for the stores drawn from ration dump include: Bread (for mice), one loaf per day for 25 mice; milk (for mice), one tin per day for 25 mice.

Although military organization as described by Lieutenant Smart may not be necessary for civilian work, we would call attention to the remarks made by Professor Sir John Cadman in a foreword to the book under review. He says: "It is clear that rescue work in collieries would be conducted more efficiently and with less danger by the application of some, at least, of the rules and regulations and by the adoption of the standardized system of training which were employed by the military authorities in connexion with the rescue operations conducted by the Tunnelling Companies of the Royal Engineers during the war."

Wherever noxious or irrespirable gases may be met with, rescue apparatus is a necessity, and in dealing with warehouse fires, gas undertakings, coke-ovens, and chemical works trained men equipped with self-contained breathing apparatus may be able to save life and property. Lieutenant Smart has written a book which will go far towards supplying the needs of those who desire to study self-breathing apparatus and the organization of mine rescue work. In these times of trade depression it is gratifying to note that Messrs. Charles Griffin & Co. have added so valuable and original a volume to their well-known series of textbooks for mining engineers.

STANLEY NETTLETON.

The Tin Resources of the British Empire. By NORMAN M. PENZER, M.A., F.G.S. Cloth, octavo, 350 pages. Price 15s. net. London: William Rider & Sons, Ltd.

This book is a compilation of extracts from articles and bulletins by some of the leading geological and mining authorities on tin, and gives in a concise and attractive style all the known localities within the British Empire where tin occurs. While the author acknowledges his indebtedness to these various authorities, the work would carry greater weight if quotations and extracts were more clearly defined instead of leaving the reader in doubt as to which parts, if any, are written from the author's own experience.

The book opens with an introduction giving a brief historical sketch of the etymology of the word "tin", and its early sources and uses, together with a list of the ores containing tin. Chapter II deals with the geology and occurrence of tin in the United Kingdom, with special reference to the principal mines in Cornwall and Devon, now unfortunately closed down owing to the depressed state of industry. Of geological interest is the occurrence of tin in Scotland and Ireland, but in neither case are they of economic importance.

A large part of the book is taken up by Chapter III, relating to the tin-producing British possessions in Asia, one of which alone, Malaya, has by far the largest output in the world. The author deals thoroughly with this important section under different headings, but one cannot leave unnoticed some few inaccuracies that appear. On p. 56 it is stated that "malaria is not common", whereas it is very common, but fevers of the malignant type are rare, and consequently the mortality is low compared with other tropical countries. Under "Methods of Mining" the word "lampan" is bracketed with "dredging", from which one would naturally infer that "lampan" is the

equivalent of "dredging", whereas it means "ground sluicing". Muddy water does not assist concentration, as the author states on p. 73, but rather impedes it, while the statement on p. 77 that wolfram is removed from tin-tungsten concentrates by means of a horse-shoe magnet is an error which should not have been allowed to creep in. Dredge buckets, too, are usually seven to twelve rather than ten to twelve cubic feet capacity.

Several interesting photographs illustrating the methods of working are given and the section ends with a number of tables of output, charts of production and export of tin over a period of thirty years, and a glossary of a few Malay-Chinese words used in mining.

Of the Indian Empire the Burma deposits are, as the author points out, the most important, while, apart from geological interest, the tin occurring in Bengal and Bombay is negligible. Interesting historical and geological data are given of the Mergui and Tavoy districts, development of which has been slow owing to the lack of means of communication, but according to the table on pp. 146 and 151 a pronounced increase in the output is noticeable in recent years.

The African colonies and the newly acquired "German South-West Africa" are dealt with in Chapter IV, with Nigeria as the most important producer. Here the deposits are in many respects similar to those of Malaya, though by no means so rich or so extensive, and their development was retarded by labour and climatic conditions. In the historical sketch the author states that it was in 1884 that tin was first brought to the notice of the Governor of Northern Nigeria, though from the table showing the output it was only in 1907 that tin was mined in any quantity. He attributes this delay to the public being slow in taking advantage of the situation (p. 161), but he might have also added to a great extent to the lack of sympathy shown to the industry by the Government, who failed to realize that the miner is one of the forerunners of civilization. Since this book was written, representations made to the Government to help the industry have received favourable consideration, and the promised construction of additional railway lines will greatly assist the development of deposits now too far distant for profitable exploitation.

In Chapter V Canada is mentioned on the meagre evidence that tin has been found there, but this chapter could well have been omitted from the book. Tin has doubtless been found in other British colonies, but this would hardly justify their inclusion in the book as being important to the resources of the British Empire.

Chapter VI deals with Australasia. The various tin-producing countries are well described, and the accurate maps are helpful in following the description of the fields. The latest statistics of the Commonwealth are not complete, but there is a distinct falling off in the output.

Chapters VII and VIII describe the industrial application of tin and prices of the metal, ending with a table of the world's output, which might have been brought up to a more recent date than 1917. The heading of the table "Tin Ore (Tin Content)" on p. 294 is misleading, as the figures relate to either the quantity of metal produced or to its equivalent in the ore, and not to tin ore.

The unprecedented demand for tin, created by the war, caused its price to rise to a fabulous figure, which acted as an incentive to increased production, more especially in those countries unaffected by the high taxation to which companies operating in the British Empire were penalized. The result was a large increase in the production of tin in foreign countries, which reaped all the benefits of the high prices. Thus, while in 1914 the production in the British Empire amounted to 57%, in 1918 when the price had risen to close on £400 per ton, the production had fallen to 44% of the world's total output. This high-water mark in the price of tin was reached in the early part of 1920, when the metal sold for £419 per ton, and the subsequent decline to the present level, far below the cost of production, has caused a falling off of the output which is bound to be reflected in an advance in the price so soon as the industrial world returns to more normal conditions. The statistical evidence presented shows this gradual decline in the production of tin in the British Empire, and therefore great efforts will be needed to retain the supremacy in the world's supply which we have held in the past.

An excellent bibliography completes an interesting and instructive book, which should prove helpful both to the general public and to the student in acquiring a knowledge of the tin resources of the British Empire. A somewhat similar work on the Tin Resources of Foreign Countries, as foreshadowed in the general introduction, would fill a much-felt want. HENRY BRELICK.

Field Methods in Petroleum Geology. By G. H. Cox, C. L. Dake, and G. A. Muilenburg. Cloth, octavo, 310 pages, illustrated. Price 24s. net. New York and London: McGraw-Hill Book Company.

The progress of modern methods in field geology as applied to oil-finding has been extremely rapid of latter years, more particularly since the value of scientific investigation of petroliferous areas has become generally recognized. The tendency has undoubtedly been towards the creation of a highly specialized field technique, involving an intimate knowledge of accurate geological mapping, a knowledge only attained after extensive personal experience. The opening up of several new areas all over the world has further necessitated the initial construction of topographical maps as preliminary to geological work, and in many cases the geologist has had to act as his own surveyor, usually a matter of regret, though not without obvious advantages in many cases. It follows, therefore, that the training of an oil-geologist must at least include instruction in the first principles of surveying, in order that, if need arise, he may be able to use the ordinary instruments necessary to the production of a topographical map on which to base his future work. We are thus able to appreciate the reason of the two distinct sections into which the present volume is divided, the first dealing with instruments and instrument methods, and the second with the structural geology of petroleum, including identification of structures and general field operations.

The chapters on surveying are, if anything, more lucid and comprehensive than those devoted to actual geological field work; from the antithetical nature of the two sciences this was rather to be expected, since any discussion of field methods, unless extensive, is bound to lend itself to much adverse criticism from the very nature and magnitude of the subject. The proof of this lies in the fact that no really exhaustive treatise on structural geology has ever been written, and if it were it is doubtful whether it could adequately replace even a part of that training which actual field experience gives, and from which ability and competence can alone be won. The authors have attempted a very ambitious task in the production of this book, and although it certainly fills a gap in technical literature as intended, it hardly comprises a "satisfactory systematic discussion of the minutiæ of field procedure" (to quote the preface), even applied to oil geology. Such a discussion, if at all feasible, would fill a book many times the size of this little volume.

In the chapter on instruments, compasses, levels, barometers, alidades, levelling and stadia rods, and the plane table all receive careful treatment, and, as concise descriptive matter, this is a very commendable part of the book. The succeeding chapter is devoted to the various methods of usage of such apparatus in actual practice, and contains ample information for those unaccustomed to the handling of instruments of this description. The important initial determinations in oilfield work are those of direction, distance, and elevation, and the methods discussed rightly eliminate all details having no direct bearing on these points.

Preceding to the geological section of the book, we are at once struck by the narrowness of view taken by the authors in their treatment of the subject; for example, a statement appearing on the opening page (129) of this section reads as follows: "The field-work of a petroleum geologist is confined largely, and in wild-cat territory, almost wholly, to the working out of structural conditions of folding and faulting; in other words it is made up largely of a search for anticlines and terraces, and of the mapping of such areas." Such a statement, more especially the latter part, is not only elementary, but it shows a decided lack of imagination, to say the very least. When geologists confine their attention solely to the location of anticlines or terraces, then they may as well retire from the field altogether; if the experience of the last decade gained from many parts of the world is simply bounded by the word "anticline", it is not only a poor outlook for future oil exploration, but is at the same time a doubtful reflection on the standard of work carried out. To be of real and universal value any discussion of suitable oilfield structures and their identification should be, if not actually comprehensive, at least broad and constructive, and to narrow the possibilities down is simply to evade the wider questions.

Under the heading of field operations is included a great deal of miscellaneous information of value to a field party, as contributing both to the success of the work and to the welfare of the individual.

The volume contains a glossary of technical

terms, and also an appendix including tables of natural functions, stadia tables, temperature corrections for altitude scale, etc. In addition, there is an introduction which, in eleven pages, disposes of the origin of oil and gas, reservoirs, migration, and structural conditions favouring accumulation; the diagrams illustrating these features, showing inclined water, oil, and gas zones in some cases are indeed difficult to follow.

H. B. MILNER.

Primer on the Storage of Petroleum Spirit and Carbide of Calcium. By MAJOR A. COOPER-KEY, C.B. Second Edition revised. Cloth, octavo, 140 pages. Price 5s. net. London: Charles Griffin & Co., Ltd.

The general utility and public appreciation of this little handbook on the storage of petroleum are proved by the issue of this second edition, in which the author has revised certain parts of the text, bringing it both legally and technically up to date. The success of a publication of this description is not at all surprising, since it seems to be a curious feature of English law that, although framed for the protection and well-being of the community at large, a species of popular edition of any particular Act or Order has to be written before the tenets thereof can be grasped by the public directly affected. Usually the niceties of legal terminology and the quaint complexities of phrasing leave the layman in a perfect maze of doubt and incomprehensibility on perusal of the official documents, and it is not until his favourite newspaper gives an intelligible account, or a readable annotated version of its purport is published, that he really knows exactly what to do and what not to do. Thus, on matters pertaining to the conveyance and storage of petroleum, petroleum products, benzol, and similar inflammables (including acetylene and calcium carbide also discussed here), there must obviously be no misapprehension, since the risk of fire or explosion, particularly in densely populated districts, and the possible disasters attendant on carelessness of keeping or handling such materials, are too great to allow of any evasion of regulations through lack of understanding.

The great fillip accorded to the motor industry as a result of the war has tended to an enormous increase in the number of persons using petroleum products both in commercial and private interests; consequently a great deal more motor-spirit is privately stored than was the case a few years ago. The Act allows the ordinary consumer to keep sixty gallons in a suitable store-house, subject to the regulations made by the Secretary of State under Section 5 of the Locomotives on Highways Act, 1896, full details of which will be found in Appendix V in the present volume. The majority of people, we are sure, are conscientious in the matter of carrying out the necessary regulations, but there is always that casual minority, who either through ignorance or selfish disregard for the safety of others, declines to worry about such "trifles" as regulations, and in this case the allowance is just sixty gallons too much. The truth of the old adage that "familiarity breeds contempt" never received more cogent proof than from the long record of accidents resulting from careless handling of oil; chauffeurs as a class are particularly remiss in this respect, and we welcome the author's eight "Dont's" for their guidance. Such a practice as smoking while replenishing petrol tanks, for example, is of common occurrence; in nine times out of ten nothing untoward happens, but there is always the tenth chance.

In this book the preliminary chapter deals with oil and flash point determinations in so far as these affect the legislative control of oil. There follows a chapter on the storage of oil without licence, in essence a lucid explanation of the existing regulations. The author also deals with the various aspects of bulk storage and of the licences issued for this purpose by the local authority; the treatment of these questions is very excellent, because some valuable personal suggestions are embodied in the text, making it comparatively easy for petroleum inspectors and others to carry out their duties in the best interests of all concerned. Such features as site, construction, mode of storage, quantity permissible under particular circumstances, conveyance, and garage supplies are all adequately discussed, together with the sound modern plan of underground storage, a method finding favour with many large commercial firms at the present time. In the last chapter on future legislation, a variety of matters are discussed in which criticism and suggestion play an important part; the paragraph on tank-ships ("tankers") might well have been extended from the

point of view of general information ; it is surprising how few people have any idea whatever of the nature of the vessel conveying oil from one country to another.

Finally, the inclusion of a chapter on acetylene and calcium carbide, their properties, storage, uses, and dangers, and also the paragraphs dealing with existing legislation in regard to these matters, are entirely relevant to a book of this description. The probability is that at least 70% of motorists use acetylene lighting at the present time, despite the many obvious advantages of electricity ; under these circumstances the use and storage of calcium carbide are, with the acetylene to which it gives rise, subjects just as worthy of careful consideration and regulation as petroleum.

H. B. MILNER.

NEWS LETTERS

BRISBANE

March 30.

ROMA OIL GEOLOGY.—For the last year or so Dr. H. I. Jensen has been studying the geology of the Roma district in South Queensland, 300 miles west of Brisbane. This is the locale of the much-discussed and celebrated Roma bore, which is being sunk by the State authorities. A report by Dr. Jensen has this month been published by the Queensland Department of Mines. He has, since May, 1920, been investigating the geology of a considerable area of country north of the Western Railway between Roma and Mitchell. So far, the examination of the country has been carried north to the Carnarvon Range, where the tributaries of the Comet River rise, and to Crystalbrook and Eddystone Vale stations, roughly 100 miles north of the Western Railway. The work has been beset with difficulties owing to the scarcity of rock outcrops over considerable areas ; nevertheless, the main features of the structure of the region have now been disclosed. A full account of the country with geological details is being prepared for publication as a Bulletin of the Geological Survey. A brief résumé of the principal results of the investigation are given herewith.

The geological formations embraced in the area examined are : (1) the Ipswich series of the Jura-Trias, consisting of sandstones, shales, calcareous shales, limestone (impure), and calcareous tuff occupying a fringe along the extreme north of the area, and dipping south-west under (2) the Bundamba series (also Jura-Trias), consisting principally of sandstones, mostly of a siliceous type, conglomerate and some intercalated shale ; this latter series spreads over the greater part of Pony Hills, Westgrove, Merivale, Crystalbrook, and Eddystone Vale stations, and dips southerly and south-westerly under (3) the Walloon (also Jura-Trias) series, which extends from Forest Vale, Toolumbilla, Mount Hutton, Myall Downs, and Durham Downs stations on the north almost to the railway line between Roma and Wallumbilla, and to within 12 miles north of the railroad between Amby and Mitchell. South of the Walloon there is (4) the Cretaceous Marine. Areas of rock which has been assumed to be (5) Upper Cretaceous, on the ground of lithological character and stratigraphical position, but destitute of fossil evidence, have also been determined north of Mitchell ; and (6) the basalts of Mount Hutton and the Dividing Range have been mapped more accurately than hitherto.

In Bulletin 247, p. 17, Mr. W. E. Cameron estimates the dip of the Trias-Jura beds under the Roma region at between 150 ft. and 200 ft. in the mile towards the south. In the present investigation the average southerly dip in large areas of massive sandstone on the Dividing Range north of Orallo was found to be somewhere between 1 in 45 and 1 in 50, that is, between 105 ft. and 120 ft. in the mile. Observations in the field on Crystalbrook and Eddystone Vale stations gave the southerly factor of dip as 60 ft. in the mile for this region.

In a section prepared an average dip of 1 in 50, or about 100 ft. to the mile, to the south was assumed. It was noticed that this brings the gas zone at the bottom of the Roma bores into the heart of the Injune Creek coal area or Lower (calcareous) Walloon division. In fact, the Roma gas zone seems to coincide with that of the "bore-hole coals" passed through between the surface and 400 ft. in depth in Nos. 3 and 3A water bores on Mount Hutton subdivision, about 8 miles west of the 51 mile on the Injune Railway. A comparison of the strata passed through in these bores and those of the Roma bores shows that both consist of a rapid alternation of shale, carbonaceous shale, sandstone, and limestone, with occasional hard streaks, cements, etc., with this difference, that the Injune sections show

frequent intercalations of coal as well. The rapidly changing nature of the deposits indicates formation under estuarine and deltaic conditions, therefore favourable for the production of oil. The two Injune Creek bores referred to also yielded gas, which, however, on analysis, proved to be coal gas.

Inasmuch as Cunningham Craig has shown in the case of the Trinidad field, and other geologists for other fields, that a coal series may within a few miles change into an oil series, there is no objection to the correlation of the Injune Creek coal beds with the Roma gas zone. In fact, all the geological evidence collected points to the identity of the two zones. Thus, the rocks actually met with in the field passing north from Roma, and plotted on a section assuming the average dip of about 100 ft. to the mile, give almost the same thickness of each horizon passed through as in the Roma bores. In reality the dip is not as regular as assumed above. Field work shows that the entire region is folded into gentle anticlines and synclines on approximately north-south axes, and that there are a series of monoclines and flattenings, or terraces passing from south to north which have developed on east-west axes.

To deal first with the rolls on north-south axes, it may be mentioned that there are indications of a syncline of a very gentle nature between Roma and Wallumbilla. Roma is near the axis of a gentle anticline, but would appear to be slightly (perhaps 3 to 4 miles) east of the actual centre. A broad syncline has its centre near Muckadilla, as shown both by the curvature of the Cretaceous Walloon border north of Muckadilla, and by the section of the Muckadilla bore. Another anticline has its axis a few miles west of Amby, but there are indications of a severe north-south fault, with downthrow to the west, between Amby and the sharp bend in the Dividing Range. This downthrow moves the boundary between the Cretaceous and Walloon many miles north of where it otherwise would be.

As regards the monoclines or terraces, there is a very decided flattening of dip at Orallo and Cornwall about 30 miles north of the Western Railway. There is a slight increase in dip from the 35 mile to the 50 mile, and a great flattening between the 50 mile and the 62 mile on the Orallo line. The dip steepens again north of Injune Creek, and noticeable dips are frequent as far as Baffle Creek and Westgrove, but the beds lie almost horizontal in the Dawson River near Boxvale and north of Boxvale to the Carnarvon Range. In this range they steepen very considerably, the southerly component often exceeding 6 degrees.

Of all the formations met with through the entire region, those outcropping in the Injune Creek basin show most freely the characters of an oil series, as regards nature of sediments and mode of deposition, as well as in the saline nature of this belt as compared with the other belts. It was stated by many cattle men that cattle do not require salt on the Mount Hutton (Injune Creek) runs, whereas both south and north of this belt salt is necessary. There were, however, no signs noticed either of oil exudations, or of asphalt, bitumen, earthwax, or any other result of the evaporation of the liquid fractions of oil, on which one can definitely assert this area to be an oilfield. In the records of the water bores put down by the Public Estates Improvement Branch, which kindly supplied all the particulars they could, there is frequent reference to "oily shale" having been passed through. Some of the muds out of bore 3A, which were seen by Dr. Jensen, were of a greasy nature, and floated as a dark dirty scum on top of the water; but as drilling was not in progress at the time to enable him to get an uncontaminated sample no analysis of these scums has yet been made. They are probably only carbonaceous muds. Several drillers consider that they noted a smell of kerosene in boring in various parts of the district, but such evidence is of little or no value. It would be much better if the drillers would make a practice of taking a sample of the drillings and forward them to the Mines Department for analysis, when they think they see indications of oil.

The apparent absence of earthwax, ozokerite, solid paraffin, etc., may be due to the Injune Creek beds being coal measures only in this region, but it is also quite possible that such substances will yet be found. Much of the country is covered with dense brigalow and belar scrubs. Brigalow is a timber which grows on heavy clays such as are found in association with coal seams. It probably covers most of the outcrops of coal seams, and if there were any oil or paraffin exudations in the district the odds are greatly in favour of their being hidden in brigalow scrubs. Discoveries may yet be made by the new settlers who are clearing and exploring their holdings.

If the negative evidence of the water bores on the Mount Hutton settlement be not considered to rule out the probability of oil in this district, boring for oil should be located east of the 49 mile in the Dividing Range near the head of Eurombah Creek, this being, as far as can be gauged, the axis of the meridianal anticline. But this is 8 miles or more from the railway line. Orallo seems to be a very favourable place for oil drilling on the railway line, since not only is it on a terrace of the east-west folding, but the dips around Orallo and Cornwall show a tendency to a local dome near Orallo.

However, preliminary diamond drilling, to determine the exact locus of the anticlinal axes, where much oil drilling is intended, would be highly advisable to ensure the oil bores being placed on the best sites. This is, in fact, what Mr. Cameron recommended in Publication 247. These bores need not be deep—only deep enough to cut some easily recognized horizon. It is quite impossible to determine the exact locus of anticlines by field observations owing to the paucity of outcrops.

There are three important horizons for coal in the Walloon. The first is met with in the Upper Walloon division, outcrops in Bungeworgorai Creek near Nareeten, and is met with in the Roma bore at a depth of 700 ft. to 800 ft. The coal is inferior, and very high in ash, occurs in thin bands, and the country rocks are exceedingly friable, making very bad standing ground. The next coals occur in a considerable thickness of rocks met with at depths of from 1,800 ft. to 2,400 ft. beneath Roma. They are Middle Walloon, and outcrop at Orallo, Cornwall, and Alcurah. The coals are high in ash, contain frequent bands, and occur in rocks which crumble so much on exposure to air that they are the worst of standing ground. Moreover, the coal bands are very variable in thickness at comparatively short distances.

The next coal series is that of Injune Creek, which appears to be represented by the gas and possible oil series under Roma. It is Lower Walloon, and contains scores of small seams (met with in the Injune Creek bores) and some large seams. They appear to thin out and thicken in comparatively short distances as is usual with estuarine sediments. The quality of the coal is very good in some of the seams, and the country rock in this division forms far better standing ground than in the higher measures.

The most easily accessible, and apparently also the best, seam so far located is one occurring in Boyd's and Ferguson's wells west of the railway line between the 56 and 59 mile and in other wells and water bores east of the railway, which seem to indicate an extent of at least 3 miles by 3 miles. There is, according to Mr. Boyd, 3 ft. of clean coal in his well underlain by 6 in. shale and between 6 in. and 1 ft. of coal below. The analysis of this coal from Ferguson's well yielded moisture 5%, volatile matter 40·5%, fixed carbon 49·7%, and ash 4·8%. The depth of the coal ranges from 40 ft. to 100 ft. below the surface in the area mentioned, and the thickness is generally mentioned as about 4 ft.

The Walloon area appears to contain numerous seams of kerosene shale, little specimens of which are often said to have been found in the creeks. Dr. Jack mentions kerosene shale as occurring somewhere on Injune Creek. Dr. Jensen did not obtain any specimens there, but in Bungeworgorai Creek, near the junction with Stewart Creek, occurred a bed of oil shale, which was probably 2 ft. in thickness, but only 1 ft. of the thickness was clearly exposed above the muds and talus under the bank. This shale, analysed by the Government analyst, yielded 44·8 gallons of oil to the ton.

It is obvious, therefore, that there are both good oil and coal possibilities in the Walloon measures, but development is retarded through the fact that outcrops are so rare. Diamond-drilling alone can absolutely determine the best way to exploit the mineral resources of this region.

VANCOUVER, B.C.

April 27.

Mining in the Yukon.—The Yukon Gold Company has developed a 9 ft. vein in its No. 9 tunnel, at Keno Hill, in the Mayo district. Two feet in the centre of the vein is solid galena, running upwards of 200 oz. per ton in silver, while the ore on either side is carbonate, also rich in silver. A winze has been sunk 75 ft., and a rise put up to the surface, also 75 ft., without any appreciable alteration in either the character or tenor of the vein. The company has more than 2,500 tons of ore sacked and delivered at Mayo Landing, awaiting the opening of navigation. The ore will average 200 oz. per ton in silver and between 60 and 70% in lead.

A wealthy United States syndicate, headed by F. W. Bradley, of the Bunker Hill & Sullivan, has bonded a number of claims in the Mayo district. A number of claims have

been bonded, too, by other United States syndicates. There will be much activity in the district during the coming summer.

A start is being made in placer-gold mining, and the operations will be more extensive this year than for any year since the commencement of the war. The Yukon Gold Company will open its 70 mile ditch, and by the aid of syphons and flumes will carry water to its Gold Hill diggings, above the town of Grand Forks, on Bonanza Creek, where extensive hydraulicking will be done. The company, too, will operate a dredge on Gold Run Creek. The Canadian Klondike Company will have three large dredges in operation, and the North-West Corporation two smaller dredges. These two companies will be under one management.

Consolidated Mining and Smelting.—The annual report of the Consolidated Mining & Smelting Company of Canada, Ltd., shows the mines and plant of the company to be in excellent physical condition, though, of course, like practically all other concerns of a similar nature, the company has an enormous supply of metals on hand. The report shows that during the year ended December 31, 1920, the quantity of ore treated amounted to 592,762 tons, and the following quantities of metals were produced : 42,636 oz. of gold, 1,097,930 oz. of silver, 23,474,652 lb. of lead, 4,501,594 lb. of copper, and 36,995,394 lb. of zinc. Considerable improvements were made in the method of dressing the Sullivan mine ore, resulting in more easily treatable lead and zinc concentrates, and, consequently, in increased recovery of metals and in reduction of cost of extraction. Owing to labour troubles the Rossland mines were closed for part of the year, and consequently the gold and copper output was less than it otherwise would have been. The copper smelter and refinery was worked intermittently, and, as a result, the costs in that department were greater than usual. Most of the tonnage for the lead plant was provided by the Sullivan mine in the form of crude ore, concentrate, and lead sulphate residue from the zinc plant. Considerable improvement was made in the electrolytic zinc plant, with the result that in the month of December the output was brought up to 5,000,000 lb. for the month, by far the greatest monthly output that the plant has ever made.

Some important new discoveries were made by development work at the Sullivan mine. An extension of the workings on the No. 11 level has opened up a large body of ore running high in zinc with a fair average lead content. Diamond-drilling from the bottom level has proved the continuity of the rich ore that was so profitable in the upper workings. During the year the mine produced 242,294 tons of zinc-lead ore, 13,214 tons of lead ore that was sent direct to the lead furnace without preliminary treatment, and sufficient iron pyrites to supply the needs of the sulphuric acid plant. The Rossland mines produced 50,841 tons of smelting ore and 3,683 tons of concentrate. A 2,500 ton concentrator had been designed for the treatment of the low-grade ore from these mines, and it had been the intention to erect the plant during the year, but labour troubles at the mines made it advisable not to go on with the work.

During the first three months of the present year 101,898 tons of ore has been received at the Trail smelter, compared with 73,236 tons for the corresponding period of last year. There is this difference, however, that while a large proportion of the receipts for the first quarter of last year was from independent mines, 98% of the receipts during the first three months of the present year was from the company's own mines. The Consolidated is still carrying a large surplus of metals, but it is said to be finding an outlet for its zinc in the Orient. The company has a considerable advantage in this trade, as the C.P.R. boats ply between Vancouver and the Orient, and consequently the freight charges are all in the family, so to speak.

Granby Consolidated.—After an inspection of the Granby Consolidated Mining, Smelting, & Power Company's properties, H. S. Munro, general manager, announced that the Grand Forks property has been completely closed, and all detachable machinery had been removed to the company's other properties or had been sold. The Hidden Creek mines and Anyox smelter are being operated nearer to capacity than any other copper concern in North America. A large Dorr thickener is being installed at the coal-washing plant at the Cassidy colliery, and a powerful fan is being added to the colliery equipment. Mr. Munro stated that the colliery investment was not paying 5% and the company would gladly lease or sell it at a reasonable figure. The coal does not produce a satisfactory metallurgical coke.

Other Mines in Kootenay.—Outside of the Consolidated Company's mines, there is little activity in the Kootenay district ; as

soon as one mine starts operations, another one seems to close. The difficulty of having no outlet for the ores is too heavy a burden for the majority of operators. The Silversmith mine, which ceased production last fall, but which has kept about forty men at development work throughout the winter, closed at the beginning of April. On the other hand, the Standard, at Silverton, recently sent two cars, and the Whitewater, at Retallack, one car of ore to the Bunker Hill & Sullivan smelter at Kellogg. In both instances the ore was shipped by lessees. Lessees at the Florence mine, at Ainsworth, have some 700 tons of ore on the stock piles, awaiting the time when the Trail smelter is again in the market for custom ore. It is not of high grade, and will not stand freight charges to Kellogg unless the owners of the Florence carry out their idea of putting a steamer and barges on the lakes for the purpose. The Rambler-Cariboo Mines, Ltd., issued its annual report recently, which showed a balance of $10,157, after paying $25,000 for the Jennie claim, acquired last year. Labour troubles and water shortage prevented the mine being worked for more than half of the year. Some 4,000 tons of ore was milled, and 250 tons of zinc and 220 tons of lead concentrate produced.

Premier Mine.—Mild weather has again spoiled the sledding between the Premier mine and Stewart, in the Portland Canal division. It is doubtful, at this time of the year, whether there will be sufficient frost to put the road in condition again this season. Taken as a whole, the season has been a fair one, but the weather uncertainties have clearly demonstrated the impossibility of a big mine relying on snow and frost in north-west British Columbia as the only means by which its ore can be sent to the market. By the time what is now at the wharf is shipped close to 3,000 tons of ore will have been sent to the Tacoma smelter this winter. The value of the ore shipped runs between three and four hundred dollars per ton. Good progress is being made in clearing the right-of-way for the aerial tramway. It is expected that the concentrator and cyanide plant will be in operation by midsummer. The Algunican Development Company, a Belgian concern, which next to the Premier Gold Mining Company was the biggest employer of labour in the district last year, seems to be in financial difficulties. The men it left to develop the Spider group, which it held under option, are suing for back wages totalling $4000.

Alluvial Gold.—With cost of labour and supplies reduced, it is probable that there will be a revival of gold mining in the Province this year; in fact, the returns for the first three months of the year at the Government assay office, in Vancouver, which are 55% greater than for the same period of last year, show that even as early as this in the season there is considerable activity. The fact is, of course, that there is a great deal of unemployment and no immediate likelihood of the coppper mines that have been closed re-opening; consequently many miners, rather than remain idle, have gone to the gold diggings, and already some interesting fresh discoveries have been made, which goes to show that there is money to be made from the old Cariboo gravels yet. Two men won $400 worth of nuggets in a few days near Spence's Bridle, on the North Thompson River, and then sold the claims for $12,000. The heaviest nugget weighed more than an ounce. The fact that a number of claims and mines have been bonded and substantial deposits paid, seems to augur activity in lode-gold mining also. The Independent and the Pioneer, both in Lillooet division, have changed hands recently, and the Nugget, at Sheep Creek, is being re-opened.

Platinum.—George Clothier, resident mining engineer for the No. 1 district, reports the discovery of platinum associated with bornite and chalcopyrite in veinlets in diorite at Morsby Island, one of the Queen Charlotte group. Whether the discovery is of more than scientific interest is not yet known.

Fluor-spar.—The Consolidated M. & S. Co. has closed its Rock Candy fluor-spar mine, the demand for the concentrate produced having ceased. Most of the product of the mine was sold to steel companies at Garry, Indiana. The company also used the fluor-spar for making hydrofluosilicic acid.

Oil-drilling.—The Hon. T. D. Pataullo, Minister of Lands, has announced that the Government has let a contract for a 2,000 ft. bore-hole at the south fork of the Red River, 20 miles north-west of Hudson Hope, in the Peace River region, to Lynch Brothers, of Seattle. The bore is to be sunk at the suggestion of Professor John A. Dresser, of Montreal, who made a reconnaissance survey of the oil possibilities of the district last summer for the Provincial Government. Oil seepages have been reported from Burns Lake on the Grand Trunk Pacific, and arrangements have been made to explore the dis covery with a drill.

TORONTO

PORCUPINE.—With labour and electric power sufficient for all requirements the spring has witnessed a great increase in mining activity. The Hollinger Consolidated is working to full capacity, treating about 3,300 tons of ore every 24 hours, with a force of 1,450 men. Underground development is proceeding at the rate of about a mile per month, and the output for the current year is likely to approximate $10,000,000. In order to provide against shortage of power in the future, the Company has applied to the Ontario Government for the privilege of developing electric power at Kettle Falls, on Abitibi River, some 60 miles from the mine, which is capable of generating 35,000 h.p. The application is likely to be granted, subject to a reservation of 10,000 h.p. should it be needed for public utilities.

At the Dome Mines the new ore-body encountered on the eighth and tenth levels has been driven on for 400 ft., and proved to be from 18 to 20 ft. in width, carrying an average gold content of $25 to the ton. The extent and richness of this deposit has changed the character of the mine, which has hitherto been regarded as a low-grade proposition. The mill was designed for the treatment of low-grade ore, and the treatment of the high-grade ore now being developed will involve some alterations in the milling equipment and practice.

The McIntyre has placed orders for the machinery required to double the present capacity of its mill, which is 600 tons per day. It is to be delivered and installed before December 1. Diamond-drilling has indicated the extension of the vein system of the Hollinger on the McIntyre property below the 1,000 ft. level.

The Bewick-Moreing holdings in a central position have been taken over by the Goldale Mining Co. The Tommy Burns, some ten miles south-east of the producing area, has been placed under option, and will be explored by diamond-drilling. The Ankerite Extension, not far from the Dome, has changed hands, and will be subjected to exploration. The Northern Canada Power Co., in order to prevent a power shortage in the winter season, is constructing a conservation dam at Kemoganissee Lake, on the Mattagami River, which, it is estimated, will give a minimum extra supply of 1,500 h.p.

KIRKLAND LAKE.—Work is being speeded up in the gold mines of this camp. The supply of power has been increased from 2,000 to 4,500 h.p., and the demand is increasing so rapidly that further additions to the equipment are likely to be needed shortly. The Kirkland Lake Proprietary (1919), in which British capital is largely interested, which is a merger of the Tough-Oakes, Sylvanite, and Burnside in the Kirkland Lake field and the Aladdin Cobalt, has resumed work on the Tough-Oakes and Burnside, which are being unwatered preparatory to an examination by S. C. Thomson, of New York, who has been appointed consulting engineer. The new mill of the Wright-Hargreaves, with a capacity of about 160 tons, has been put in operation, and is treating about 125 tons daily. A force of 85 men has been engaged. The mill of the Lake Shore during March treated 1910 tons of ore with a yield of $21,675. Important results have followed development on the 600 ft. level. No. 1 vein was cut having a width of 12 ft., the ore showing higher mineralization than on the upper levels. More recently vein No. 2 was cut on the same level, carrying ore stated to be very rich. A stope opened up on the 400 ft. level contains 18,702 tons of ore, averaging upwards of $28 to the ton. The Kirkland Lake is carrying on diamond-drilling from the 900 ft. level to determine the geology at depth. An important feature in connexion with recent development is that the ore-bodies at the lower levels are found to extend to greater lengths than in the upper workings. New York interests have secured control of the Minaker-Kirkland, adjoining the Lake Shore. Some 200 ft. of driving has been done at the 165 ft. level, with encouraging results. The Ontario-Kirkland is excavating a site for its mill, which will have a capacity of 100 tons per day. A substantial quantity of ore running from $15 to $20 gold to the ton has been blocked out.

COBALT.—Silver production is gradually increasing, though the low price of silver has a discouraging effect and many properties remain closed. The Nipissing during April mined ore of an estimated value of $142,610, and shipped bullion valued at $177,762. The annual report for 1920 showed net profits of $1,279,091, which was only about half of those of the two preceding years. The surplus was $3,817,043. The production of silver was 3,332,303 oz., the cost of production being 37·4 cents per oz. The ore reserves had decreased from 6,354,000 oz. to

3,568,000. President E. P. Earle stated that explorations had been lacking in results, and that shareholders must realize that they had run into lean years. The Mining Corporation of Canada has remodelled its reduction plant, giving it a capacity of 300 tons of ore daily, as compared with the former rate of 200 tons. A small force of men has been put to work on the Buffalo property, and preparations are being made for a general resumption of activity. Active development has been started at the Silver Leaf, adjoining the Crown Reserve. At the Bailey a promising vein has been encountered in a rise from the fifth level, the silver content being stated to run 1,200 oz. to the ton.

Gowganda.—There is some revival of activity in this area, where very little work was done during the winter. The main shaft on the Castle property of the Trethewey, now down 180 ft., will be sunk to the 300 ft. level, as the high-grade veins on the 165 ft. level are continuing downwards. The Miller-Lake O'Brien, which was forced to curtail production owing to power shortage, is now in full operation, working three shifts. Several properties have been re-opened, including the Saunderson, Gowganda Enterprise, McAlpine, and Powerful, and others are preparing to resume activity.

Boston Creek.—Mining is practically at a standstill in this area. The Miller Independence, the only important company in operation, closed down last month for want of funds, after carrying on energetic work for months endeavouring to locate the downward extension of a rich vein on the 500 ft. level. The directors have authorized an issue of bonds to the amount of $50,000 to finance further development.

LETTERS TO THE EDITOR

The Camborne War Memorial

The Editor :

Sir—We venture to encroach on your columns for the purpose of aiding a good cause, namely, the establishment of a War Memorial to fallen Camborne Students. Old students are scattered to the ends of the earth, and are difficult to reach for that reason. By the medium of the Magazine we hope to be able to get into contact with them.

The Committee desire to raise at least £1,000, towards which about £200 has been subscribed to date. It is proposed to purchase the old ground on which so many of these men played in days gone by, and to equip it in a manner fitting to their memory ; in addition some form of memorial tablet is to be erected in a suitable place.

An early response is desirable, as a chance of securing the ground has presented itself which may not occur again.

The cause is a good one, and our appeal is not only to all old students but to the many other good friends of Camborne Mining School.

H. W. Hutchin.
Stanley B. White.
Honorary Secretaries.

The Mining School,
Camborne, *May* 25.

Wave-transmission Rock-drill

The Editor :

Sir—Reading the letter of Mr. R. de H. St. Stephens in your issue of May, an impartial observer trying to arrive at a correct conclusion as to the respective advantages of the old and new methods is struck by the unfair obstacles raised by Mr. St. Stephens against the wave-transmission system. He assumes certain definite conditions common to both systems and enumerates the necessary plant in each case. May I point out that a mine about to be equipped would not generate current at a voltage greater than that permissible for use at the motors, as the expense of high-tension switchgear at surface and underground, and transformer underground, could not possibly be justified except where the current was generated at a central station and distributed over large areas.

Then, in calculating the overall efficiency of the wave-power, while Mr. St. Stephens is extremely generous in allowing 93% efficiency for the generator, he deducts 5% for line drop in shaft cables. This is quite impossible, as a conductor in which 5% drop occurred in 1,000 ft. could not carry the current without overheating. 1½% would be the most economical figure.

As I have shown above, the 2% transformer loss is eliminated and the 5% cable loss is now reduced to 1½%. The figure 779·25 h.p. available at motor terminals now becomes 825, and drilling capacity becomes 343 ft. per minute. On Mr. St. Stephens' figures this still leaves an advantage with compressed air of 464 to 343.

But in a practical application of wave-power to a mine it is inconceivable that a separate motor and generator would be used for each drill, and with increasing

capacity of wave generators it naturally follows that the efficiency will increase.

The most bigoted advocate of compressed air would hardly maintain that a 12 h.p. air-compressor would supply 5·8 cubic feet of air compressed to 80 lb. per sq. in. per horsepower. In effect Mr. St. Stephens is comparing a compressed-air plant of 1,000 i.h.p. with a wave-power plant of 12 h.p. This to the mind of one who has no axe to grind, but who, in common with a vast body of mining men, is anxious to determine the true facts of the case, is manifestly unfair.

A practical demonstration of the two methods on the same rock face, with carefully recorded figures by independent observers, appears to be the only true comparison.

Would either party undertake the ordeal?

CHAS. R. LOVE.

Lanner, Redruth, May 18.

PERSONAL

R. F. ALLEN has returned from Senegal.

C. V. ANTHONY has been elected a director of Henry Bath & Son, Ltd.

G. W. CAMPION is here from West Africa.

THOMAS P. CARR has been appointed manager for the Compania Minera Anglo-Hispana Matallana, Leon, Spain.

E. H. CLIFFORD, one of the consulting engineers of the Central Mining-Rand Mines group, is in London.

W. A. DOMAN has been appointed with W. LANG joint editor of the *Financial News*. Mr. DOMAN is well-known among mining men as a sound and conscientious journalist.

C. J. EMERY is here from Broken Hill.

J. W. FINCH has been visiting the Rand and the Congo, and is back again in New York.

COLIN G. FINK, lately director of the research laboratory of the Chile Exploration Co., has opened an office at South Yonkers, New York, as consulting metallurgical engineer.

A. W. HOOKE has completed his engagement with the Bisichi and Forum companies, Nigeria, and is now staying at Tunbridge Wells.

C. J. INDER, of Inder, Henderson, & Dixon, has left for Colombia.

J. W. KIRKLAND is acting as president of the South African Institute of Engineers, in the absence of James Whitehouse.

DOUGLAS LAY has been appointed manager of the Le Roi No. 2 Mine, Rossland, B.C.

WALDEMAR LINDGREN, professor of mining geology in the Massachusetts Institute of Technology, is visiting Bolivia.

E. P. MATHEWSON left on his return to the United States on May 25.

A. W. NEWBERRY has returned to New York from Nicaragua.

J. M. NIALL, chairman of the Mount Morgan Gold Mining Co., is here from Australia.

DR. ERNEST FOX NICHOLLS has been appointed president of the Massachusetts Institute of Technology.

WALTER R. SKINNER, the editor of the *Mining Manual*, celebrated his seventieth birthday last month.

ACHESON SMITH has been elected president of the American Electro-Chemical Society.

DR. A. W. STICKNEY is back from Spain and Algeria, and has gone to the United States on a short visit.

W. E. THORNE has returned from the United States.

L. VAUGHAN has opened an office at Kroh, Upper Perak, and is in control of the work at the Betong group of mines in Lower Siam.

A. J. WALTON, manager of Crown Mines, is here from Johannesburg.

JAMES WHITEHOUSE is here from the Rand.

W. B. WORTHINGTON has been elected president of the Institution of Civil Engineers.

CHARLES WILL WRIGHT passed through London last month on his way from Italy to the United States.

The following have been appointed by the Secretary for Mines to serve on the Advisory Committee for the Metalliferous Mining Industry. Mining Engineers: THOMAS FALCON, F. H. HATCH, FRANK MERRICKS. Metallurgist: F. W. HARBORD. Economic Geologists: T. C. F. HALL, HENRY LOUIS, MALCOLM MACLAREN. Representatives of Tin Mines: R. ARTHUR THOMAS, JOSEPH HARRIS. Representatives of Lead and Zinc Mines: ANTHONY WILSON, JAMES WIGNALL.

GEORGE BLAKE WALKER, a well-known Yorkshire mining engineer, died on June 1. He was at one time a partner in the firm of Bainbridge, Seymour & Co. A year or two ago he served as President of the Institution of Mining Engineers.

AMBROSE MONELL, who was for fifteen years president of the International Nickel Company, died on May 2. He graduated from Columbia University in 1896, and his first appointment was with the Carnegie Steel Company. His name is associated with the natural copper-nickel alloy now in commercial use under the name of monel metal.

TRADE PARAGRAPHS

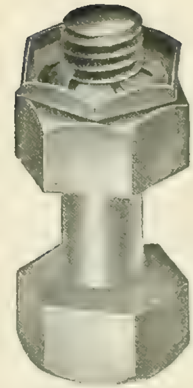
METROPOLITAN-VICKERS ELECTRICAL CO., LTD., of Manchester, send us their pamphlet No. 7875/2 describing electro-motors suitable for driving looms used in textile mills.

THE DENVER ROCK DRILL MANUFACTURING CO., of Denver, Colorado, send us a pamphlet describing the "Waughoist", a portable hoist driven by compressed air, particularly adapted for use in development operations underground.

THE WESTINGHOUSE ELECTRIC INTERNATIONAL COMPANY, of New York, send us their monthly magazine for May. This gives interesting information relating to trade in Japan, Buenos Aires, and Chile, and publishes articles on electric fans and on electric substations in France.

THE BRITISH ROPEWAY ENGINEERING CO., LTD., of 34, Fenchurch Street, London, E.C. 3, have obtained an interim injunction against Stavers & Partners, whereby the latter undertake not to carry on the business of erecting or supplying crane cables and ropeways and aerial transporters, and not to use in connexion with their business the name of "Bleichert" or "Bleichert's System" or in any way to represent that they are carrying on the business formerly carried on by Bleichert & Company.

THE PALNUT SAFETY LOCK WASHER.



THE PALNUT IN PLACE.

THE SULLIVAN MACHINERY COMPANY, of Chigaco, and Salisbury House, London, E.C. 2, send us three new pamphlets. No. 77A describes the firm's portable mine-car electrically driven air-compressors. No. 77B gives particulars of the angle-compound power-driven air-compressors; belted WJ 3, WI 3, WJ 4, direct-connected WN 3, WN 4. No. 72E describes the company's drill-sharpeners for hammer-forging drill-bits and shanks.

THE PALNUT CO., LTD., of 6 Great St. Helens, London, E.C. 3, are putting on the market a new safety lock washer, called the "Palnut". This washer is placed on top of the nut, not under it. Pressures can thus be varied at will, and the washer is easily detached when desired. The flanges are cut to fit in the base of the pitch of the thread. Being in contact with the core, they resist pressure from the nut face, with the result that the whole hexagon tends to flatten out, thus preventing the nut becoming unseated or lost. The thread of the bolt is in no may stripped or burred, and two threads of the bolt suffice for the action of the washer. The washer is particularly adapted to mining machinery, where there is much vibration. The accompanying illustrations show the washer and its position on the bolt. The price is low; for instance, the washer for an inch bolt is sold at thirty-seven shillings per gross.

THE CONSOLIDATED PNEUMATIC TOOL CO., LTD., of 170, Piccadilly, London, W. 1, have opened a branch office at 8, Clive Street, Calcutta, under the management of Captain E. Grigg, where a stock of air compressors, oil engines, and portable tools, both pneumatic and electric, together with all necessary spare parts and accessories, are kept to enable customers' requirements to be immediately filled. Full particulars as to the erection and operation of this company's well-known Giant Semi-Diesel Oil Engines can also be obtained from Captain Grigg. G. & A. Angus, of Rangoon, and the United Engineers Ltd., of Singapore, have been appointed agents for Burma and the East Indies respectively, and they will carry stocks of the labour-saving appliances manufactured by the Consolidated Pneumatic Tool Co., Ltd., so that inquiries and orders in these areas will receive immediate and prompt attention.

THE INGERSOLL-RAND CO., London office, 165, Queen Victoria Street, London, E.C. 4, send us the following information relating to a record made by No. 18 Ingersoll-Leyner drills: Some time ago a remarkable record was made by a miner by the name of Ellitson, at the Geduld mine, with No. 18 Ingersoll-Leyner drills. The Union Corporation now announce that this same miner broke his previous world's record with the same three machines in the same grade of rock and the same stoping width. The record which he has just made during the month of April is as follows: Type of drill, No. 18 Ingersoll-Leyner drills; number of drills, 3; total machine shifts, 78; total fathoms broken, 221; fathoms per machine shift, 2·83; tons broken per machine shift, 45; stoping width, 63 inches. As Mr. Ellitson has used these same drills for a considerable length of time and made remarkable fathomage in four consecutive months last year, that is, August, September, October, and November, he deserves a great deal of credit for making special efforts to break his own record with these same machines. Ordinarily a man asks for new machines whenever he wishes to make a special record. This figure of 2·83 fathoms per machine shift is an excellent performance, and is believed to stand unequalled in the world to-day under the same conditions, and not using more than three drills.

METAL MARKETS

COPPER.—The standard copper market in London during May exhibited a steadily rising tendency till towards the end of the month, when a rather easier tone manifested itself. At the beginning of May an attempt was apparently made by certain American interests to squeeze the standard market, and heavy purchases of near metal caused the market to assume a rather artificial aspect, and a backwardation made its appearance. About the middle of the month, however, the squeeze was abandoned, although some American influence was still manifestly at work supporting values, and later on the backwardation (premium commanded by cash over three months) dwindled considerably. In the meantime the American market began to firm up, and from 12¾ cents the price rose to 13¼ cents per lb. The rise in the United States was attributed to a healthier export demand, chiefly from Germany and Japan, but domestic consumption in the United States was disappointing. The artificial condition of the standard market during the month was well illustrated by the fact that not only was electrolytic at one time practically saleable as standard, but

best select was nominally quoted below standard. The April imports into the United Kingdom were 11,413 tons against 9,889 tons in April last year.

Average price of cash standard copper: May, 1921, £73 5s. 10d.; April, 1921, £69 8s. 11d.; May, 1920, £96 18s. 1d.; April, 1920, £103 2s. 11d

TIN.—The standard tin market in London fluctuated to some extent during the past month, but on the whole the tendency was firmer. Quite a feature was the freer market in the Straits, where fair quantities have been sold at prices not greatly above the London parity. With the coal strike in progress, domestic consumption was even less than had previously been the case, and it can only be concluded that most of the interest taken recently in the metal on 'Change has been of a professional character. In the East fair quantities were sold almost daily, and shipments from the Straits during May showed a fair increase over the April figures. The premium commanded by Straits metal on the London market has diminished considerably. It is understood that the F.M.S. Government has renewed its agreement with the Dutch holders in Batavia to hold the accumulated stocks for a further three months. In America the price has been firm during the month. Owing to the coal strike, production was practically suspended at the English tin smelters during the month. The United Kingdom imports of tin in April were 317 tons, against 1,440 tons last year. America has only bought spasmodically, and apparently consumers there are not doing much. The Continent shows a fair amount of buying interest. Generally speaking, consuming interest is small and supplies ample,. but the stocks are all well held.

Average price of cash standard tin: May, 1921, £177 10s. 8d.; April, 1921, £164 0s. 11d.; May, 1920, £295 3s. 7d.; April, 1920, £345 13s. 1d.

LEAD.—The London lead market during May was fairly firm, and values rose appreciably till towards the end of the month, when an easier feeling set in. The firmness was caused to some extent by the small arrivals of metal owing to vessels holding off from English ports on account of coaling difficulties. The rise in values caused some consumers to buy small quantities, but others, finding their operations curtailed by the coal stoppage, actually featured as sellers. Consuming demand, on the whole, was, in the circumstances, fair. Spain continued to be the sole supplier of virgin lead, the United States, Mexico, Australia, and Burma sending nothing. As regards America, that country herself has been buying heavily from Spain, apparently in anticipation of the increased import tax which it is expected may be imposed shortly. The position in Spain is still obscure, and the extent of the stocks there is unknown. It appears quite possible that the higher price which is now obtainable may stimulate production once more, and in this connexion it is interesting to observe that the Mexican lead-producing industry is showing signs of greater animation.

Average price of soft pig lead: May, 1921, £23 7s. 3d.; April, 1921, £20 16s. 10d.; May, 1920, £39 3s. 2d.; April, 1920, £40 4s.

SPELTER.—The month of May saw considerable firmness in the London spelter market, and prices rose somewhat. This, of course, was chiefly due to the paucity of new supplies, which more than counterbalanced the extreme poorness of demand. With the galvanizing trade in a very depressed condition, which was further accentuated by the coal stoppage, very little consuming buying could be expected, but, nevertheless, a steady, though small, consuming inquiry trickled in. As regards supplies, Germany was unable to send anything owing to the prohibitive 50% import duty imposed by the Allies, and furthermore the insurrection in Upper Silesia would have in any case hindered the output of the zinc industry there. Belgium has been offering a little metal rather above the London price, and her production is still decreasing, being only 4,320 tons in April, against 4,640 tons in March. Norway is also willing to sell, but at higher prices than rule here. In its annual report the Vieille Montagne Co. makes the remark that Europe is now only producing 150,000 tons of spelter yearly, instead of 650,000 tons. The output in the United States during April was approximately

16,500 tons, against 45,000 tons in April last year. Stocks in America are estimated at something like 80,000 tons. The Anaconda Copper Mining Co. has reopened a portion of the Washoe smelting workings to treat silver-zinc ores, and a production of 2,000,000 lb. of zinc monthly is planned.

Average price of spelter: May, 1921, £27 6s. 7d.; April, 1921, £26 1s. 5d.; May, 1920, £46 0s. 9d.; April, 1920, £48 9s. 4d.

ZINC DUST. — The market is very quiet, and present prices are about: American, £55 per ton; English, £55; and Australian, £55.

ANTIMONY.—Prices asked by first hands for English have kept steady, ordinary brands being quoted at £37 to £40 and special brands at £38 5s. to £42. Foreign material seems easier, there being sellers at £24 10s. ex warehouse.

ARSENIC.—There is practically no demand at the moment, and Cornish white is quite nominal at £46 to £48 per ton, delivered.

BISMUTH. — The quotation is steady at 7s. 6d. per lb.

CADMIUM.—Business is dull, with sellers quoting 6s. to 6s. 3d. per lb.

ALUMINIUM.—British interests are nominally quoting £150 per ton for both home and export, but Continental metal has been offering during the month at around £110, f.o.b. Continental ports.

NICKEL.—The leading producers quote £185 delivered for home business, and £185, f.o.b., for export orders.

COBALT METAL.—The price has been weak, and metal is obtainable at 15s. to 16s. per lb.

COBALT OXIDE.—A reduction of 4s. per lb. has been made in quotations, black oxide being quoted at 12s. and grey at 13s. 6d. per lb.

PLATINUM AND PALLADIUM.—Prices keep steady. Manufactured platinum and palladium are priced at £20 per oz. Raw platinum is stated to be obtainable at £17, and raw palladium around £15.

QUICKSILVER.—The tendency of late has been slightly easier, and the current quotation is £11 to £11 5s. per bottle.

SELENIUM.—The quotation continues at 10s. 6d. to 13s. per lb.

TELLURIUM.—Sellers quote 90s. to 95s. per lb.

SULPHATE OF COPPER.—The present quotation is about £30 per ton for both home and export business.

MANGANESE ORE.—The tendency has been rather easier, and Indian grades are quoted at 1s. 2½d. to 1s. 3d. per unit, c.i.f., U.K.

TUNGSTEN ORES.—Some slight signs of a recovery have been visible in this market recently, but the present price of 65% WO_3 is quoted at about 12s. 6d. to 13s. per unit, c.i.f.

MOLYBDENITE.—Business is dull, and the price has had a downward tendency. We call the quotation 47s. 6d. to 57s. 6d. per unit, nominal.

CHROME ORES.—African and Indian grades are steady at £5 10s. to £6 per ton, c.i.f., U.K.

SILVER.—The silver market in London during May was chiefly dependent for support on India, which country bought moderately. There was some liquidation by China, however, which caused weakness about the middle of the month Spot bars opened on May 2 at 34⅞d., rose to 35⅛d. on May 7, fell to 33¼d. on the 20th, subsequently recovered to 34⅛d. on the 30th, and closed on the 31st at 33¾d.

GRAPHITE.—Madagascar, 80 to 90%, is steady at £20 to £25 per ton.

IRON AND STEEL.—Business in the iron and steel trades during the past month has been virtually at a standstill owing to the prolongation of the coal strike. As regards Cleveland pig iron, no alteration was made in the official minimum quotations, but with stocks of No. 3 foundry iron being gradually diminished, owing to the cessation of production, those who had anything to sell were asking a premium of 10s. for home trade and 15s. for export. Thus the official quotation remains at £6, which price was fixed at the beginning of April. In the finished iron and steel trades, there has really been no alteration, either in the position or in home trade quotations, but with the Continent—mainly Belgium and latterly Germany—securing good export orders, British makers have started to cut quotations for shipment. They still have a long way to go, however.

THE MINING DIGEST

A RECORD OF PROGRESS IN MINING, METALLURGY, AND GEOLOGY

In this section we give abstracts of important articles and papers appearing in technical journals and proceedings of societies, together with brief records of other articles and papers; also notices of new books and pamphlets, lists of patents on mining and metallurgical subjects, and abstracts of the yearly reports of mining companies.

THE SEARCH FOR OIL IN WESTERN CANADA

The *Bulletin* of the Canadian Institute of Mining and Metallurgy for April contains two papers on the search for oil in Western Canada, presented at the March meeting of the Institute, one by John Ness, geologist for Imperial Oil, Ltd., and the other by E. M. Kindle, a member of the Canadian Geological Survey. It should be mentioned that Imperial Oil, Ltd., is a subsidiary of the Standard Oil Company, and its chief business is oil-refining at Vancouver, Regina, Sarnia, Halifax, and Montreal. We quote that part of Mr. Ness's paper dealing with Alberta and Great Slave Lake. As we quoted Dr. Bosworth on the Mackenzie oil find last month it is not necessary to refer in detail to the part of Mr. Ness's paper on this subject, or to Mr. Kindle's paper.

The area which the Imperial Oil Company is testing extends from the plains of Saskatchewan on the east to the foot-hills of the Rockies on the west, and from the international boundary on the south to within the Arctic circle. This vast extent of territory may be conveniently divided into three groups, in which the geological features are so dissimilar that each carries its own particular problem. First, there are the Cretaceous rocks of eastern Alberta and Saskatchewan, practically undisturbed and heavily covered by glacial material. Secondly, the folded and faulted Cretaceous of the foot-hills belt, the outer folds of which give a certain amount of promise structurally. Thirdly, the Devonian of the Mackenzie Valley in which oil has recently been struck.

As regards the geology of the plains of eastern Alberta and western Saskatchewan the structure is monoclinal, although there are certain local irregularities and undulations, and evidence of two general lines of folding. The first of these, which is the continuation of the structure found in the Sweet Grass Hills of Montana, probably extends north to Bow River. The second crosses the Alberta-Saskatchewan boundary south of Macklin and trends north-west. The efforts of the Imperial Oil geologists have centred upon these known, or assumed, lines of folding or faulting which previous investigation has indicated as likely to repay attention ; but a general survey—of necessity, hurried and incomplete—has been made of the whole region as far north as Lac la Biche, south to the international boundary, east to Battleford, and west as far as the Cretaceous rocks are exposed. Most of the exposures in this vast area were visited and examined, a task entailing, in many places, more travelling than actual geological work, owing to the dearth of rock sections. Hundreds of square miles have been traversed without a single outcrop of bedrock being seen, the streams having simply cut their courses in the extremely thick glacial deposits. Nothing revolutionary was discovered during these surveys, the previous work in the area leaving little to the imagination. Attention was devoted principally to the selection of suitable locations for testing the oil possibilities, those areas where the minor folding and crumpling would conceivably create conditions suitable for the accumulation of oil, and the supposed crests of the broad arches which bring the sands of the Dakota nearest to the surface being studied in detail. Previous development in this area has resulted in the hope that oil will be found in commercial quantities provided the drilling is carried to a sufficient depth. Various gas horizons have been successfully tapped and shows of oil have been encountered, and it is only by exploring the lowest beds of the Cretaceous and, if necessary, the Devonian, that these hopes will be either realized or dissipated. The drilling now in progress, or under consideration, should prove to be a fairly conclusive test. Work is being carried on at the following places: In Saskatchewan, near the international boundary, south of Cypress Hills ; on the Saskatchewan River, north of Swift Current ; at Muddy Lake, south-west of Unity ; in Alberta, south of Monitor in the Misty Hills, and near Czar at Tit Hills. Apart altogether from the commercial aspect, the drilling of these wells will be of immense interest to geologists. Starting in the Bearpaw (Pierre) or the uppermost beds of the Belly River, they should, if carried to completion, give a reliable and unique record of the Cretaceous sediments below these horizons and furnish interesting information regarding the attitude and character of the underlying Devonian.

As regards the second division of territory, although exploration in the foot-hills belt was also confined largely to rocks of Cretaceous age, the problems arising differed greatly from those of the plains. At the same time, the two areas have much in common, principally in the amount of attention that has been devoted to them by geologists, and the abundance of literature that has been given to the public. Many prominent geologists have dealt with the various aspects of this area, and one need only turn to their reports to obtain an edifying account of their researches.

The geologists of the Imperial Oil Company set out on their mission well grounded in the general features of the territory. They knew that the Cretaceous rocks had been intensely folded and faulted in proximity to the Rockies, and that, as one travelled eastward, the effects of the great upheavals, complementary to mountain building, gradually diminished until the sedimentary rocks were eventually found in such an attitude as to give favourable structure for the accumulation of oil. Not only so, but rocks, recognized elsewhere as bituminous, were known to underlie the area within convenient reach of the drill. Starting from the international boundary, they followed and mapped these outer folds into the Peace River district, and traversed that river from above Hudson's Hope to 30 miles below Peace River

Landing, the development around the latter place giving this a special interest. As in eastern Alberta, the activities of the geologists were directed mainly to those points which previous research, either by the scientist or by the driller, had brought into prominence. The Calgary boom of 1914 was marked by a great deal of rash speculation and misdirected "wild-catting". There were certain redeeming features, however, notably the development of Western Canada's first producing oilfield in Turner Valley, west of Okotoks. The vast amount of drilling that was undertaken by the various mushroom companies at this time neither proved nor condemned south-western Alberta as an oil-producer. Most of the wells were located at the whim of the driller and without any regard to geological conditions, while those which might have given a fair test were abandoned, owing either to drilling troubles or to lack of funds. The bursting of the bubble left the field discredited to a certain extent in the eyes of the public, but still interesting to the well-informed oil-man. That Imperial Oil still have faith in the future of the area may be gathered from the fact that they have acquired scattered leases over a large area on representative structure, and are drilling, or preparing to drill, a series of wells that should prove an ample test of the foot-hills belt. On a structure designated the Twin Buttes anticline, two wells are being drilled, one within a few miles of the international boundary and the other slightly to the north. On the Willow Creek anticline, west of Nanton, a third well is being drilled, while an endeavour will be made to deepen a well, taken over from another company, in the same territory. All these wells started in Benton shale and production would be looked for in the Dakota, although sandy places of the Benton might give shows of oil.

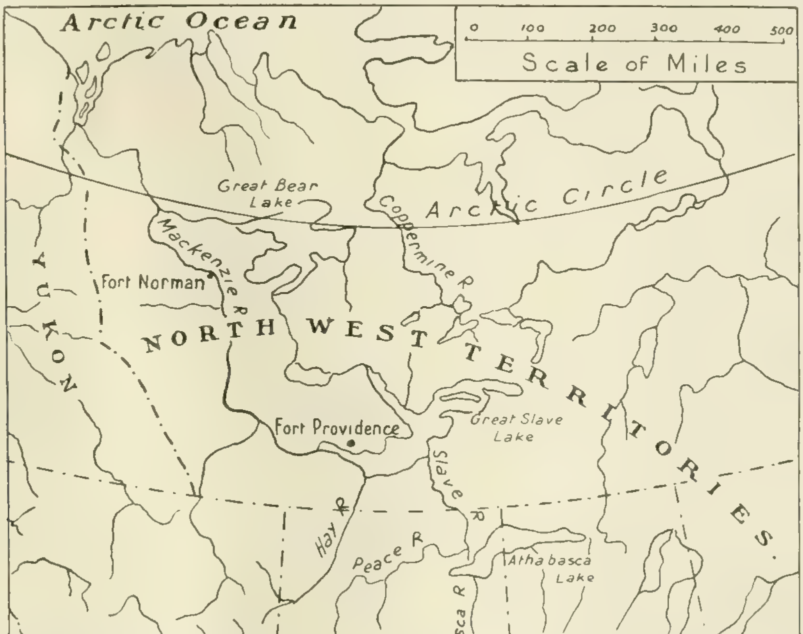
Thanks to the enlightened policy of the government in throwing open the forest reserves to oil investigation, other promising areas have been made available and will probably be tested in the vicinity of Coalspur. Here the structure exposes Belly River strata with very steep dips, and gas seepages have been noted. Deep drilling will probably be necessary, but the chances of obtaining production from the Benton, or even from the lower beds of the Belly River, are not to be overlooked. Favourable indications for oil are found near Pouce Coupe, the rocks at the surface being probably equivalent to the Lower Pierre of eastern Alberta. A test will, in all probability, be made there. Regarding the present field of activity at Peace River, success, if it does come, will probably be attained in the Devonian, the Cretaceous rocks having been drilled into, and through, without exceptional results. There are other structures in the vast area under review that offer possibilities of oil and gas production. It is hoped that other companies will be sufficiently impressed with their possibilities to test them, so that in the near future it may become known whether this area is destined to become a producer of oil or not.

The author proceeds to deal with the Mackenzie River Basin. Exploration of the basin of the Mackenzie dates back to the latter part of the eighteenth century, since which time periodic attempts, more or less successful, have been made to collect information regarding its extent, physical features, and mineral wealth. The full story of these adventures is written in the pages of Canadian history, and the illustrious names of those early *voyageurs* are perpetuated in memorials not made by hands. The geologist was well in evidence in the story of these adventures, and such names as Dawson, McConnell, Bell, Tyrrell, Dowling, Camsell, and Kindle, to mention only a few, are closely connected with the activities of the pioneers. The first investigation of the area on behalf of the petroleum industry, however, was not undertaken until 1914, when Dr. T. O. Bosworth, latterly chief geologist of Imperial Oil, Ltd., covered the whole district from the cities of Alberta to the Arctic Ocean. Dr. Bosworth's paper before the Institution of Petroleum Technologists was quoted in last month's MAGAZINE.

Although the war intervened to hold up development, the project was naturally not lost sight of, and in 1919 two rigs were shipped into the country to locations previously made by Dr. Bosworth, one at Windy Point on Great Slave Lake and the other, destined to become famous, at a point 40 miles down stream from Fort Norman on the Mackenzie. Along with the drilling crews were two parties of geologists who devoted the short season at their disposal to a more careful study of the rocks in the vicinity of the drilling operations. Both drilling and survey work were continued during 1920, the former coming to a promising conclusion in August, and the geologists finding themselves merely on the verge of great areas demanding careful study and painstaking work before their geological history can be written.

In travelling northward on the great waterways the Devonian formation is first found at Crooked Rapids on the Athabasca. Associated with these limestones are "tar sands". The natural oil indications along the Athabasca River are probably the most extensive and conspicuous in the whole world. For a distance of 100 miles a bed of tar sand from 150 to 220 ft. in thickness is almost continuously exposed along the sides of a gorge-like valley, and in many parts cliffs of the tar rock rise steeply from the water's edge to a height of 200 ft. From the exposures on the Athabasca and its tributaries, and by deduction, the existence of the tar sands may be reasonably assumed over an area of 10,000 square miles, probably the largest deposit of asphaltum in the world. The tar sand is a sandstone formation saturated with a dark viscous oil. Originally the rock must have been an ordinary bed of current-bedded sandstone, with some shaly courses, and plant-bearing in places. Courses of finer sandstone or sandy-clay rock, seams of lignite, and thin lenticular seams of concretionary limestone are occasionally found, while, at the base, there are sometimes ferruginous pebbly beds with little oil. As seen at the outcrops, it is a black or dark-brown rock containing from 10 to 30% (by volume) of heavy oil; it is soft and somewhat plastic and, in some instances, oil can be squeezed out by hand. In places, heavy, tarry oil issues slowly from the cliffs and accumulates in holes dug in the outcrop. Chemical analyses show this oil to be of fairly good grade, the chief trouble at present being that it is so viscous that it cannot be pumped from the wells. It has been supposed that the asphaltic material seen at the outcrops of the tar sand is the residue from a vast body of oil from which the light constituents have evaporated. This assumption has led to the drilling of a number of wells back from the outcrop of the sand, with the hope of finding a lighter grade of oil. These hopes have not been realized, however, as the oil found was

almost as viscous as at the outcrop of the sand. It seems possible that, eventually, an oil industry may be established in the Athabasca tar sand region, but whether this will be the result of totally unique methods of extracting the oil from the wells to circumvent its high viscosity, or whether the chemist will devise a means of extracting the oil from the sands by retorting, will only be demonstrated by the march of events.



MAP OF WESTERN CANADA TO ILLUSTRATE THE OIL DEVELOPMENTS.

Nothing need be said of the geology along the waterways until Slave Lake is reached. Travelling eastward from Fort Providence along the shores of that lake, no solid rock is found until after passing Slave Point. On the east side of this is a deep bay about 5 miles wide, having a beach formed of limestone fragments which have been derived from outcrops under the water near at hand. Crossing the bay Brule Point is reached, where the land stands at a higher level. A raised beach, or really a succession of raised beaches, of limestone debris occurs at this place and is traceable eastward for some miles. At Brule Point the waves of the present lake have cut into the older shore-line, forming a cliff about 18 ft. high, capped by loose stones. The lower part of the cliff is composed of fine grey limestone, fissile in parts, smelling strongly of petroleum and containing ill-preserved corals, alveolites, brachiopods, and gasteropods. The same rocks are exposed beneath the water. At Windy Point there are heavy beaches, old and new, consisting of limestone fragments (all

more or less petroliferous but the solid rock is not exposed. About 1½ miles from Windy Point, however, the solid limestone is again seen beneath the water and then for 2 miles further the only evidence is in the beaches. A portion of the shore is now reached where for 3 miles the solid rocks are conspicuous, forming a ragged coast-line with scars of limestone reaching far out into the water. The beds are still dipping in the same direction, but the rock consists of a rough bedded dolomite-limestone of crystalline structure and porous texture, saturated with fluid petroleum which is seeping into the waters of the lake, giving rise to a distinct film of oil on the surface at most parts of the shore for several miles. Where met with inland, for a distance of half a mile, the rock exposures contain small pools of asphalt and oil. Gas seepages have been noticed on the shore and small sulphur springs exist. There is no evidence of structures, and the thickness of the beds is unknown. They have been referred to the Middle Devonian and denominated "Slave Point limestone" and "Presqu'ile dolomite" respectively, and would probably correlate with the Beavertail and Ramparts limestone of the Mackenzie. In the valley of the Hay River, Cretaceous beds, approximately of the same age as the Loon River shales, are found, and also members of the Upper Devonian correlated with the Chemung and Portage. The well now being drilled at Windy Point should give some interesting data regarding the thickness and character of the underlying strata.

DIAMONDIFEROUS BRECCIAS IN BRAZIL

The *Transactions* of the Geological Society of South Africa for 1920 contains a paper by David Draper, the doyen of diamond geologists, on the high-level diamond-bearing breccias at Diamantina, Brazil.

The gravel beds of the Jequitinhonha river, which takes its rise in the Serra do Espinhaco, a few miles south of the town of Diamantina, were, for over a century, the chief source whence diamonds were obtained. During the slave-holding period many thousands of labourers were employed in washing the diamond-yielding gravels, thereby producing wealth to their owners, as well as enriching the impoverished treasury of the Portuguese Government. The discovery of diamonds in the Jequitinhonha dates from the year 1729, and the yield of wealth from this source has not ceased, though greatly diminished, up to the present day. Though the recent river gravels, as well as the ancient terraces, contained a rich crop of diamonds, no one endeavoured to trace the source whence these gems were derived, until an accidental discovery, made by a slave woman, of diamonds in a blue clay on the summit of the watershed that divides the Jequitinhonha and the Sao Francisco rivers, drew attention to the brecciated beds which were situated on the higher ridges flanking the Jequitinhonha. The first of these discoveries, named the St. Joao do Chapada, was exceedingly rich in parts, and subsequently many similar areas were investigated with encouraging results; but owing to the want of water on these high-lying areas, they have all been neglected for many years; yet the future of the diamond industry in Brazil is intimately connected with their development.

The Serra do Espinhaco, rising to a general altitude of about 1,400 metres, with occasional peaks reaching to nearly 2,000 metres, lies about 200 miles inland, with its greatest length, over 1,000 kilometres, roughly parallel with the Atlantic Coast, and its greatest width about 90 kilometres. On the west the Serra do Espinhaco is flanked by the valley of the Sao Francisco river.

The Serra is composed of alternating beds of quartzite and shale of about equal thickness; owing to the severe tilting to which the whole series has been subjected, these beds dip at a general angle of about 45° to the eastward, and in consequence the tilted outcrops of the softer slate beds have been lowered by the forces of atmospheric erosion, and now form flat-bottomed valleys, lying between ridges of quartzite several hundreds of feet high. These valleys continue for short distances in straight lines, but have been forced out of line by numerous cross faultings; crumpling in a most intricate form is occasionally seen, both in the quartzite and in the slates. The quartzite is generally very fine grained, and made up almost entirely of small grains of white quartz; where unweathered it is extremely hard, but decomposes into a soft friable sandstone. The slate beds are generally yellow in colour, distinctly laminated and soft. Those situated near the town of Diamantina are red in colour, and somewhat resemble the Hospital Hill slates of Johannesburg in mineral composition. Conglomerate beds, formed of rounded quartz pebbles in a siliceous cement, are occasionally met with in the quartzite. They closely resemble the conglomerate of the Witwatersrand in appearance, but do not contain gold.

The general aspect of the Serra do Espinhaco is that of a rugged rocky plateau, scored by narrow ravines, of great depth, with precipitous sides. Innumerable ridges of low altitude run parallel with the strike of the formation, and these consist of quartzite, weathered into most fantastic outlines and deeply scored and fissured. A scant vegetation covers the flanks of these ridges, and the valley bottoms; but in general only rock is visible in the higher elevations of the landscape; where slate beds predominate, the valleys are covered with coarse grass and semi-aquatic vegetation. Land suitable for agriculture occurs in small areas in the valleys, but these are few and far between. In such a rugged and desolate country means of communication are bad; beyond the railway station at Diamantina the traveller has only mule transport to depend on for the conveyance of his baggage and himself.

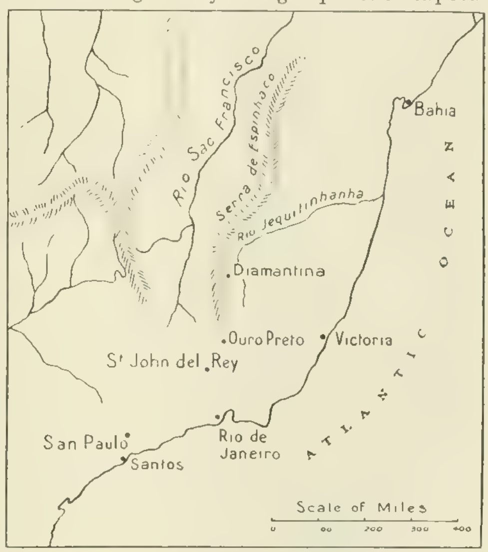
When the earlier diamond seekers discovered that the small tributaries of the Jequitinhonha yielded diamonds, they continued their operations until they extended beyond the level of the water supply. The crude methods then, and still in use, prevented any higher workings; hence the summits of the diamond-bearing mounds remained intact, except in the most favourable localities. By this method many high-level diamond-bearing areas were discovered. The best known of these in the neighbourhood of Diamantina are St. Joao do Chapada, Sopa, Boa Vista, Serrinha, Datas, and a few other of minor importance.

St. Joao do Chapada has been inspected by most of the leading geologists who have visited or been residents of Brazil. Dr. Orville A. Derby, late

State Geologist to the Federal Government of Brazil, in a pamphlet published in 1898, deals fully with the aspect of the great cutting (500 metres in length by 40 in depth) and the occurrence of the diamonds in three distinct veins, one of which was of pegmatitic origin, and the occurrence of kaolin. Unfortunately Dr. Derby did not analyse this mineral. Hausser and Claralz declared the mineral to be hornblende, but Rose failed to find this mineral in the sample examined by him. Later on Harder and Chamberlin, in 1914, described the cutting, but they also refer to the mineral, both at St. Joao do Chapada, as kaolin. Unfortunately they were not able to inspect the mine as the cutting had fallen in, and had been abandoned for the past 12 years. Von Eschwege, Von Helmreichen, Gorciex, and many other noted geologists, inspected the high-level diamond-bearing breccias of Diamantina,* but none of them recorded the chief characteristics which point so conspicuously to their being a unique formation, agreeing in many respects with the kimberlite pipes of South Africa, yet possessing problems which are quite out of the common, and which, until these mines are further developed, will remain in doubt.

Boa Vista is the most extensive of these high-level breccias, and as the writer has now been resident on the property for over a year, and has neglected no opportunity to disentangle the geological puzzle which it presents, it will be described in fuller details. The Boa Vista mine is situated about 12 miles east of Diamantina. Encircled by the quartzite ranges of the Serra do Espinhaco and bounded on the north by the Rio Bon Successo, and on the south by the Rio Fundao, lies a mound about 250 ft. above the flanking valleys, and covered with a scrubby brush vegetation. Though the surrounding country consists of naked quartzite rocks, forming ranges over 1,000 ft. in height, there is no vestige of any mineral matter, other than broken quartz, and nodules of limonite in the red, grey, or yellow soil lying on the surface of the mound, which is over three miles in length and one mile in width. Many small streams flow from the flanks of this mound, and in these diamonds have been found for the past half-century. On the northern slope of the mound there are very extensive workings, occupying over one mile in length, and about 100 yards in width, and in the deepest part over 70 ft. in depth. In these workings very interesting sections of the deposit are obtainable, and they give the following succession of beds: (1) Surface soil varying in depth from a couple of feet to over 25 ft.; (2) brecciated sandstone cemented together by a soft cement; (3) highly decomposed Espinhaco quartz much disturbed, but generally dipping at low angles in various directions. On the northern slope several dykes intersect both the underlying quartzite and the brecciated bed, and where these occur the floor has been faulted, in places for over two feet. The mineral contained in these dykes is so highly decomposed that it is impossible to determine its original composition; as seen at present it resembled a soft soapstone, foliated, and scaly, unctuous to the touch, colour grey, greenish, or yellowish. The disturbance of both the floor and the brecciated beds indicates that these veins are of later origin than the brecciated bed above referred to. The brecciated bed, being the diamond-bearer, is of the greatest economic importance.

A view of any of the worked faces of the great excavation presents the following aspect: angular and sub-angular, rarely round boulders of soft sandstone, differing in bulk from pieces about six inches in diameter to masses over 18 inches in diameter, scattered without regard to size, throughout the mass, but occasionally in layers separated from each other by beds of finely granular talc. When the boulders have unequal diameters their longest section is generally vertical or steeply inclined. The boulders of sandstone are of many different colours, some black and sparkling with small bright crystals of magnetite; others chocolate coloured, red, yellow, or grey, but the light colours predominating. None is hard, but all can be crumbled to pieces by the pressure of the fingers. Rarely do the boulders touch each other in the mass; they are almost invariably separated by a grey or greenish grey cementing mineral, soft and unctuous, differing completely in mineral composition from the boulders. In the cement there are a few egg-shaped pebbles of white or grey quartz, very much fractured and generally falling to pieces on exposure.



Map of the Diamantina District.

The cement also contains magnetite, martite, ilmenite, perofskite, small books, with rounded edges, of phlogopite, a few crystals of black tourmaline, very few garnets, and diamonds. From surface to floor the whole mass is quite soft, though immediately on the sandstone bed it is generally somewhat harder than higher up. In these places an olive green mineral is distinctly in evidence, giving a characteristic colour to the mineral filling the interstices between the boulders. The cement also is harder than the boulders. Thin quartz veins are also in evidence passing from the sandstone floor for a few feet upward into the mass. Like the dykes, these are also of later origin than the brecciated beds.

A description of Boa Vista is, generally speaking, applicable to all of the high-level diamond-bearing deposit of Diamantina. The soft, soapy, talcose mineral is characteristic of them all, but Boa Vista is, owing to its vast size and the great area of old workings, the only one that can be examined to any extent. Workings on all the slopes of the mound, as well as hundreds of prospecting

pits give evidence of the continuation of the breccia with its talcose cement, and the yield of diamonds has proved it to be an area of great economic value. To this may be added that in the neighbouring rivers many falls exist where an ample supply of power can be generated ; that there is no lack of water near the mine for hydraulicking purposes ; and finally that the entire mass of mineral is soft, yielding less than 1 per cent of hard nodules. Under these conditions working expenses are very low, and as the diamonds are of the finest quality, and inferior stones very rare, this great mine, when handled by men of experience, will take its place as one of the great diamond-producers of the world.

Previous writers have all held that these beds are of fluviatile origin, and they have been called conglomerates. Only Gorciex suggested that there is no reason why the diamond may not have been formed in veins in the same manner as topaz and other minerals. This was with reference to the St. Joao do Chapada mine. Harder and Chamberlin distinctly state that these occurrences have been formed by a flowing river, and suggest that by mapping the actual course of this ancient river could be defined. The late Dr. Orville A. Derby informed the writer that he was of opinion that they were the remains of a great transgressional bed of conglomerate that covered large portions of middle Brazil, though he admitted that the Sao Francisco valley was a decided obstacle to this theory. No observer, who is acquainted with the nature of conglomerates, when examining the faces of Boa Vista mine, would for a minute consider them to be conglomerates, formed by fluviatile or glacial means. In true conglomerates the boulders would have been more rounded or egg-shaped. They would have been superimposed on each other, or at any rate more closely crowded together than they are in this bed. Then, again, the fact that the cementing mineral is of a totally different composition from that of the boulders is of very great importance, as well as the origin of the boulders from the beds surrounding the mine. Though quartzite of a very durable nature exists on the hills surrounding the mine, the boulders of similar rock have been reduced, most likely by chemical action, to incoherent sandstones. The fact that the boulders are composed of only one class of rock must also be taken into consideration as opposed to the fluviatile origin of the Boa Vista and other high-level diamond-bearing deposits. But last, and by no means least, there remains the indisputable fact that the diamonds from each individual high-level deposit possess characteristics so distinct from each other that there is no difficulty in determining their origin. Those who favour the fluviatile origin of high-level breccias will have to explain away the foregoing difficulties. A river that could not only sort out the class of boulders, provide them with a cementing matter quite distinct, and at the same time provide each area with diamonds of a different character, would indeed be a great curiosity. Though it is not difficult to bring evidence to controvert the fluviatile theory, it is quite a different matter to provide one that does justice to these unique occurrences.

The kimberlite pipes of South Africa can be so distinctly proved to be of volcanic origin that no one disputes the point at the present time. Kimberlite is largely made up of olivine. Though fresh specimens are unobtainable at any of the Diamantina occurrences, an analysis of the freshest mineral gave a high percentage of magnesia ; some crystals extracted from a groundmass of the cement showed all the characteristics of olivine ; on the other hand, there are no signs of felspar or its decomposition product, kaolin. Talc, however, is abundant in the decomposed cement. The present diamond-bearing rivers of this part of Minas all rise in the great quartzite range known as the Serra do Espinhaco. The Jequitinhonha and the Arrasonahy, both rivers of about equal size, join about 100 kilometres north of Diamantina, yet, though the former was probably the richest diamond-bearing river ever discovered, the latter is not known to contain diamonds. St. Joao do Chapada Mine is over 130 ft. deep, and the diamond-bearing mineral continues still deeper. In places Boa Vista has been worked to a depth of over 70 ft., yet there is absolutely no alteration in the nature or construction of the breccia. There is nothing to indicate that there are any talc beds in the country that could have produced the cementing matter ; all the known igneous dykes which are now reduced to a talcose mineral, are of later origin than the breccia, and consequently they could not have produced the cement. It is therefore essential that some other source of origin should be considered, and after a lengthy study of the subject the writer has come to the conclusion that certain areas in the Serra do Espinhaco, notably those in the vicinity of Diamantina, were subjected to severe dynamic forces, which resulted in the opening of fissures, these forming channels whereby the diamond-bearing mineral, probably kimberlite or some allied rock, in a highly decomposed condition, could reach the surface and where a weakness in the superincumbent strata existed, large masses were formed in the adjacent rock. These, breaking naturally into rectangular fragments, became entangled in the plastic mass, and owing to the higher specific gravity of the cement the masses of lighter sandstone remained in suspension, and were prevented from touching each other, or in many cases from reaching the bottom. A complete intersection of one of those occurrences will in all probability uncover the fissure from where the diamond-bearing mineral has reached its present position.

With the exception of St. Joao do Chapada, to which no bottom has been discovered at a depth of 130 ft., all the other occurrences are only being operated on along the flanks, where a disturbed floor occurs. On the south-western slope of Boa Vista, the Espinhaco quartzite forms a distinct wall over 60 ft. high, bounding the brecciated bed, and on the northern side a vertical wall of talcose rock can be seen to a depth of over 70 ft. ; borings have shown the depth of the deposit at this spot to be over 100 ft., where no bottom rock was encountered.

Though the high level diamond-bearing breccias of Diamantina cannot actually be called " pipes ", there is no doubt that they are of local origin, each one representing a distinct occurrence of diamond-bearing rock, consisting of a talcose mineral forming the cementing matter, in which the brecciated masses of quartzite became entangled, while the mass was in a plastic condition, and finally as there is no evidence regarding the cement having been deposited by the action of surface waters, it must be assumed for the present that it emanated from deep-seated regions and was brought to the surface

through channels, either fissures or circular vents. The Agua Suja diamond mine, situated about 300 miles westward of Diamantina, in many respects resembles the brecciated deposits of Diamantina. When this mine was inspected by the writer about ten years ago he came to the conclusion that the diamond-bearing bed was of local origin, that is to say, that it was formed by the breaking up of a mass of igneous rocks which existed in its immediate vicinity, and as the large boulders were of local origin, the smaller minerals, including the diamond, could not have been brought from distant sources, but were also of local origin. Since that visit the writer has explored the head waters of the Rio Sao Francisco and the Paranahyba, where he discovered a small kimberlite pipe near the town of Patos, and last year specimens of kimberlite were brought from the neighbourhood of Coromandel. These discoveries point to the fact that true kimberlite exists in Brazil, and confirm the author's contention that the Brazilian diamond-bearing rivers have derived their diamond contents from the disintegration of volcanic vents similar in many respects to the South African occurrences.

THE BRITISH AMERICAN NICKEL CORPORATION

In the *Canadian Mining Journal* for March 18, W. A. Carlyle, the managing director, gives an account of the operations of the British American Nickel Corporation. It will be remembered that this company has developed the Murray mine near Sudbury, Ontario, and has erected a smelter near by, together with a refinery near Ottawa, where the Swedish Hybinette process is employed. The Corporation was financed by the British Government as a war measure. Owing to the present fall in the prices and demand for metals, the mine and works were closed shortly after the beginning of this year. We give herewith Mr. Carlyle's description.

The mining lands owned by the company comprise 17,590 acres in the nickel district at Sudbury, of which 12,590 acres are located in the mineral-bearing zone. Most of the diamond-drilling campaign was confined to the Murray mine, where a very large body of ore was thus disclosed, to which all recent mining operations are confined. This ore-body, as determined by vertical drill-holes, 200 ft. apart, outcrops at the surface, and with a very uniform dip of 38° from the horizontal has been shown to extend 3,600 ft. downward on the dip with a thickness varying from 40 to 140 ft. of smelting ore. Within the area drilled lie 16,000,000 tons of ore, averaging 3% of nickel and copper, sufficient to keep the present plants running for 30 years, and the ore-body undoubtedly extends much farther beyond the holes, the deeper of which discloses a great tonnage of higher-grade ore, containing 4% nickel and copper. The ore typical of the district occurs in the norite rocks with a foot-wall of greenstone, and in places, granite; and consists of pyrrhotite with some chalcopyrite. It also contains a small but valuable amount of the rare metals of the platinum group, all of which will be recovered and separated in the refining process.

At the Murray mine a three-compartment inclined shaft in the foot-wall is now down about 1,200 ft. with eight levels opened up, each half in the foot-wall and half in the ore. A unique method of mining the ore has been chosen that will permit the cheap extraction of at least 90% of the whole ore mass. On each of the five levels is a 5 ton Canadian Westinghouse locomotive, with Edison storage-batteries, running on 24 in. tracks laid with 36 lb. rails, and hauling four 4 ton ore-cars of the Granby type. On each level is a motor-generator set for charging the batteries on the third shift. All of this plant is giving great satisfaction. The drilling is done with Waugh No. 21 turbo-hammer drills using 90 to 100 lb. air and hollow steel for water feed. There is a large ore-pocket, with finger-gates below every second level, which loads the 8 ton skips in two compartments of the shaft. On the surface all the buildings are substantial and well built. As enough electric power for the time being could not be obtained, it was decided to instal steam plants at the mine and smelter, but so arranged that every machine could later on be electrically driven. In the mine power house are three 1,000 h.p. Babcock & Wilcox boilers, 160 lb. pressure, equipped with Weir feed-pumps and large steel coal-hoppers with endless pan-conveyors, feeding the chain grates with slack coal. There is a powerful Allis-Chalmers steam-hoist of the latest design, hoisting at the rate of 1,500 ft. per minute, and two Belliss-Morcom air-compressors, each yielding, at 250 r. p. m., 2,500 cu. ft. of free air per minute at 105 lb. There are also two other small compressors, one steam, the other electrically driven, and 6,500 to 7,000 cu. ft. air is altogether available. In the shaft-house the ore from the skips, after passing over grizzlies, goes through a 46 by 48 in. Buchanan-Blake-type rock-crusher into a flat-bottomed bin, which feeds the 36 in. belt, 300 ft. long, to the top of the rock-house, where the rock, after passing over a 2 in. screen, is distributed by a belt along a storage bin, which in turn supplies the seven picking-belts. The mine can easily supply 1,200 to 1,400 tons of mixed ore per day, and 2,400 tons have been hoisted in two shifts. From 20 to 25% of the material hoisted is picked out and sent to the waste dump. The smelting ore, coarse and fine, is taken in 35 ton ore cars 1¼ miles to the smelter ore-bins.

At the smelter the power-house boiler-room contains six 1,000 h.p. Babcock & Wilcox boilers, working at 180 lb. pressure, supplied with superheaters and chain grates, also fed from steel bins filled by the endless bucket-conveyor. Weir pumps supply the boiler feed from a Cochrane preheater. In the blower-room are four turbo-blowers, 3,600 r. p. m., each direct connected to a steam turbine, blowers and turbines being the Rateau-Battu-Smoot design. Two of the blowers each deliver 30,000 cu. ft. free air each at 36 oz. for the blast-furnaces and two 36,000 cu. ft. each at 12 lb. pressure to the converters, the steam turbine for each of these being 2,200 h.p. Each turbine has its surface condenser complete in every detail with centrifugal pumps for returning the hot condensing-water to a cooling pond. One unit comprises a 1,100 h.p. turbine, driving one of the blast-furnace blowers, and a 550 k.w. generator, used when the Wahnapitae power fails, which can be used as a motor to direct-drive one or both blast-furnace blowers. On account of the highly superheated steam, 590 to 610°, it was found necessary to fit the steam governors of all the turbines with monel-metal parts, which has proved very satisfactory.

In the smelter building are two blast furnaces, 50 by 360 in. at the tuyeres, and a third is on the ground. On a strongly constructed crucible, 24 in. high, stands the single row of steel water-jackets, 14 ft. long, 30 in. wide, inner plate $\frac{5}{8}$ in., outer $\frac{3}{8}$ in., with a water space of 5 in. There are two $4\frac{1}{2}$ in. tuyeres in each jacket, or 24 on each side of the furnace. The furnace is tapped at either end, using a water-cooled cast-iron spout for discharging into a settler 20 ft. by 30 ft. by 5 ft., lined with chrome and magnesite bricks, there being three settlers in all. The four matte tap-holes at first gave much trouble, but a syphon tap, invented by J. H. Gillis, solved this difficulty. On the charging floor standard gauge tracks on each side of the furnaces lead to the supply-bins, and a specially designed type of charge-car drawn by electric trolley locomotives gives great satisfaction. Each car is divided into four 4 ton compartments, discharging one side into the four feed openings of the furnace, while in the centre of the other side is a multibeam weighing device, with which the proper weights of coke, ore, and flux can be weighed into each section through the valve-gates in the bottom of the supply-bins. In the converter aisle are two 60 ft. span, 40 ton electric travelling cranes serving the three Peirce-Smith basic-lines converters 13 by 30 ft., each with forty-four $1\frac{1}{2}$ in. tuyeres and electrically rotated. Steel ladles holding 20 tons of matte, or 12 tons of converter slag, are used. The holes soon made in these by the corrosive matte are now very successfully repaired by fitting in pieces of steel plate by thermit welding.

The smelting practice has many features different from that followed by the other smelters in the Sudbury district. The ore averaging SiO_2 24%, Fe 35%, CaO 3·7%, MgO 4·3%, Al_2O_3 6%, S 19%, is smelted without any preliminary roasting, and the only flux used is converter slag containing SiO_2 16%, Fe 52%, CaO 3·5%, Al_2O_3 3·5%, the charge consisting of 70 to 75% ore, the balance flux, with 10·5% coke on the charge. The resulting slags contain SiO_2 35·5%, Fe 30%, CaO 5·5%, Al_2O_3 13%, and 0·24 to 0·34% nickel plus copper plus cobalt. The low-grade matte from this furnace, containing 11 to 13% nickel and copper is poured into the converters, and blown up to the usual matte containing 80 to 82% copper and nickel and a trace of iron, which is transferred to an oil-fired furnace, and in running from thence through a strong stream of water is very successfully granulated, then wheeled into box cars and shipped to the refinery. In the converter method the flux mainly used is ore fines with some silicious gravel or sand. One aim is to keep the silica in the converter slag as low as possible, it often averaging for days under 13%, which eventually will become the regular practice. This slag is poured in part into large 20 ton cars, poured outside the building on to shallow beds lined with ore fines, broken up and lifted by locomotive cranes, using clam-shell buckets, and sent to the smelter bins. Part of the slag is poured into the settlers. The capacity of the blast-furnaces is proving much greater than anticipated, as for the past three months one furnace has averaged over 800 tons of ore per day, and 1,015 tons of ore have been smelted in one day, counting in the ore used as flux in the converters. In the future greater results will be achieved, especially if the ore fines under $1\frac{1}{2}$ in. now going to the furnaces are sintered, a problem now being studied. The amount of flue-dust is small, being caught in the dust flues and chambers. The smelter stack is 300 ft. high and 25 ft. inside diameter.

The refinery is situated at Deschêne, Quebec, near Ottawa, where cheap electric power was available, and other advantageous factors existed, such as an excellent site, water, and sufficent labour. This plant has a capacity of 15,000,000 lb. of nickel per annum, and at a comparatively small expense can be increased to from 20 to 24 million pounds. This metal is deposited electrolytically by the Hybinette process, and a very high-grade product is being produced, containing practically no impurities but a little iron and copper and some hydrogen. The matte from the smelter passes through two Wedge roasters, each with eight hearths, and thence to the leaching department, where the copper in part is dissolved with H_2SO_4 and plated out in the electrolytic tanks, the cathodes being melted down and cast into 81 lb. ingots; about 55 tons of copper is produced per 100 tons of nickel. The leached matte with fluxes is then smelted in especially designed electric furnaces using 24 in. circular carbon electrodes, and nickel-copper anodes, weighing 200 lb., are cast in steel moulds. These furnaces, which are proving a signal success, were designed by Ivar Hole, a Norwegian metallurgical engineer. These anodes then go to the nickel-depositing building, which covers three acres, and not only is the nickel plated out, but a large amount of nickel-sulphate and also nickel-ammonium salt is produced for sale to the nickel-plating industries. The slimes remaining after the nickel anodes are dissolved are collected and concentrated, and will be refined in the precious-metals department to yield platinum, palladium, iridium, rhodium, and some gold and silver.

HERB LAKE GOLD DEPOSIT, MANITOBA

The March *Bulletin* of the Canadian Institute of Mining and Metallurgy contains a paper by F. J. Alcock, a member of the Ontario Geological Survey, on the geology and ore deposits at Herb Lake, at the eastern end of The Pas mineral belt, Manitoba. Herb Lake is at the opposite end of the belt to Flin-Flon Lake, particulars of the geology of which were given in the April issue. The first real interest in the Herb Lake region was aroused in the summer of 1914, when gold-bearing quartz was found on the east shore of Herb Lake, on what is now known as the Kiski claim. Other finds were soon made close to the original discovery, and active prospecting has continued from that time to the present. A considerable amount of development work has been carried out on a number of claims, and on one property, the Rex, a mill has been erected and active mining operations carried on.

The rocks of the Herb Lake district belong to two geological eras. The greater part of the region is underlain by rocks of pre-Cambrian age, but a belt of Palæozoic rocks extends across the southern margin of the region. Since, however, the ores were deposited before the deposition of the Palæozoic rocks, the latter are of no consequence in this connexion. The pre-Cambrian rocks in turn fall into two main divisions: first, granite and its differentiates; and secondly, an older complex consisting of sediments and igneous rocks highly folded, and intruded and metamorphosed by the

granite stocks and batholiths. The igneous members of the pre-granite complex are, to a large extent, of volcanic origin and consist of flows, tuffs, and breccias; intrusive rocks, however, of the composition of diorites, and dykes of lamprophyre and porphyry are also found. In composition there is a wide range from light-coloured, acid rhyolites to dark-coloured greenstone rocks of the composition of basalts. In places, some of the acid types appear to intrude the more basic rocks, but they are all probably related to the same period of igneous activity. Many of the rocks have been altered into schists through regional and contact metamorphism. From basic types, chlorite schist is a common product, and from the acid types, sericite schist. Along the borders of the granite intrusions the common alteration product of the greenstone rocks is hornblende schist.

The sedimentary rocks of the pre-granite complex consist of quartzite and paragneiss with conglomeratic bands, garnet-gneisses and staurolite-bearing and cyanite-bearing schists. These rocks are interbanded with at least part of the volcanic rocks, and the whole is considered to be a thick series of interbedded flows and clastic sediments folded and metamorphosed by granite intrusions. A great erosional unconformity separates all these rocks from the flat-lying Ordovician dolomite along the southern shore of Herb Lake. A mantle of clay, laid down in post-glacial Lake Agassiz, covers much of the area and renders prospecting locally difficult. The areas of muskeg are equally disadvantageous in this regard.

The gold deposits are in the form of veins which are found traversing all the pre-Cambrian rocks of the area. They are considered to be genetically related to the granite intrusions. The evidence leading to this conclusion may be briefly cited. The granite with its differentiatesforms the youngest intrusive of the region; since quartz veins are found traversing even the granite, they have either been derived from it or from some other intrusive that is not exposed at the surface. Again, many of the quartz veins contain felspar, and a number of gradational types between true quartz veins and pegmatite dykes were found; since the pegmatites were clearly derived from granite intrusions, it is necessary to postulate a similar origin for the quartz veins. The mineralogy of the veins is also significant. Tourmaline, which is a common pneumatolytic mineral associated with granites and pegmatites, is present in nearly all the veins. Arsenopyrite is also very common in the quartz and is locally found disseminated in the granite as an original constituent. The geographic distribution of the main veins at Herb Lake is likewise suggestive. The main veins lie near the border of a granite stock which is situated between the Grass River and Little Herb Bay. This stock has produced extensive contact metamorphism with the development of garnetiferous and staurolite-bearing schist in the zone surrounding it, and has almost certainly been responsible for the formation of the veins. This suggests that the most favourable places for prospecting should be along the borders of similar stocks.

Most of the deposits are fissure veins with sharply defined walls. Along some of the veins, however, the country rock has been extensively altered, giving rise to a border zone of sulphides and carbonate rock, a zone that in places carries gold. The deposits are for the most part lenticular, with pinches and swells. Many of them follow the rock structure, either bedding or schistosity, and as a rule small stringers are parallel. The veins lie in various types of country rock; several of the important veins of the area occur in a rhyolite-porphyry, a possible reason for this being that its hard, massive character is more favourable for the preservation of fissures than the softer, more schistose rocks.

The quartz of the veins varies to a considerable extent. Many of the barren veins consist of white quartz with practically no mineralization. In the gold-bearing veins, the quartz varies from white to brownish in colour, and from granular to coarse vitreous in texture. The variety that, as a rule, carries the best value in gold is a fine, granular type traversed by dark streaks. These streaks, for the most part, are short and irregular, and along them is concentrated most of the mineralization, consisting of black tourmaline, sulphides, and the greater part of the gold. In places, however, needles of tourmaline, specks of sulphides, and gold in visible quantities are found in the quartz away from any of these dark streaks. Of the sulphides, arsenopyrite is the most abundant, but pyrite, chalcopyrite, galena, and blende are also found. Felspar crystals are sometimes found in the veins, and on the Moosehorn claim a telluride, probably petzite, was found associated with some of the gold particles. The absence of any well-banded structure in the quartz, and the association of the gold with the sulphides, and more particularly with the tourmaline, is evidence that the ore was deposited under conditions of high temperature. In a number of specimens collected, gold in visible quantities was found completely enclosed in masses of tourmaline, showing that the same origin must be assigned to both minerals.

To summarize, therefore, it is believed that the gold-bearing veins of the region are high temperature deposits genetically related to intrusions of granite. These intrusions were accompanied by deformation which produced fractures, shear planes, anticlinal openings, and other lines of weakness. As the intrusive mass cooled and commenced to solidify, the volatile constituents became progressively more and more concentrated in the remaining liquid part of the magma, and during the late stages of the intrusion, were finally given off forming pegmatite dykes and quartz veins. The formation of the veins was a process which proceeded slowly and in places the primary quartz was crushed, and minerals, including gold, were deposited in the fractured areas; but the whole was essentially one process related to the granite intrusion. Fractures would naturally be more abundant in the roof of the batholith, and it would be along these lines that the ascending solutions would escape; veins would therefore be more numerous along the upper parts of the intrusion. In the long period separating the time of the intrusion and the deposition of the Ordovician dolomite, the region suffered extensive denudation, with the result that the roofs of the batholiths were nearly everywhere stripped off and the upper parts of the batholiths themselves removed. This erosion meant the destruction of many valuable ore deposits. In other places, however, where the intrusions did not come so near the surface, erosion has uncovered only the irregular upper parts of the batholiths, parts which would appear on a surface map as small stocks. These consequently are more favourable places for

prospecting than where wide areas of granite are now found. It must be remembered, however, that any area where rocks of the pre-granite complex are exposed may be underlain at no great depth by intrusive masses and hence be mineralized. Solutions also may travel considerable distances from their parent magma. The Rex vein lies at a distance of over a mile from the nearest surface exposure of granite, and the Kiski veins at a distance of nearly 3 miles. The Twin Lakes property shows that, even in the borders of the granite stocks, deposits of ore may be found.

The only property on which active mining and milling operations have been performed is the Rex. During 1918, work was carried on from May until December, when the plant was closed. Work was resumed in the spring of 1920. The vein lies approximately 200 ft. from the shore of Wekusko lake. It strikes 20° east of north and has been traced for a distance of 1,700 ft. It maintains a width of from 2 to 5 ft. for most of its length, but at two places it swells to a width of over 15 ft., and at others it pinches to less than 1 ft. The vein follows closely a contact between a rhyolite-porphyry and a conglomeratic sediment. As far as work has progressed, the gold persists in depth; an interesting feature in connexion with the ore-shoot that is being mined at present is the fact that, so far as its outlines have been determined by sampling on the surface and underground, it seems to have vertical boundaries.

The Northern Manitoba group is a property consisting of two claims, the Moosehorn and the Ballast, on which is exposed a vein approximately 300 ft. long and varying in width from 6 in. to over 2 ft. A shaft has been sunk to a depth of 100 ft., and 50 ft. of driving has been done. One carload of ore amounting to 57,000 lb. was shipped to Trail, B.C., the returns on which amounted to $2,323, an average of $81·53 in gold per ton.

On the Kiski-Wekusko, the original discovery in the area, three main veins are exposed. No. 1 has been stripped for over 700 ft. and has an average width of 3½ ft., at one point swelling to a width of 12 ft. No. 2 has been stripped for 500 ft. and traced much farther; it has an average width of 3 ft. and at one place is 12 ft. wide. A vertical shaft has been sunk to a depth of 53 ft. on this vein. No. 3 vein has been traced for about 100 ft. It carries gold in visible quantities. Other veins and exposures of quartz have been proved to occur on the property.

On the Elizabeth-Dauphin claims, the Elizabeth vein lies 1½ miles north-east of the Rex. It has an exposed length of over 800 ft. and a width of from 2 to 6 ft. A shaft has been sunk to a depth of 50 ft.

On the Bingo, several small veins have been uncovered. The largest varies from 7 in. to over a foot in width. Gold is present in visible amounts.

The McCafferty vein has been traced by stripping and trenching for over 1,600 ft. Its width varies to over 8 ft.

The discovery on the Apex group is a mineralized zone in red granite. The rock which carries the ore is much like the regional red granite, but is lighter in colour and may best be described as a fine-grained pegmatite. It is more quartzose than the granite, and grades, by loss of felspar, into typical quartz-vein material. The contact between the pegmatite and the granite is locally distinct, but, in places, it is difficult to distinguish the two types. In such places the lode is recognized by the presence of sulphides of which arsenopyrite is the most abundant. The mineralized zone is irregular; at one place it has a width of 40 ft. In places the granite is shattered and small quartz stringers form a stockwork. The irregular character of the deposits makes it difficult to estimate its value.

ANACONDA ELECTROLYTIC ZINC

In the May issue we gave some quotations from the paper by Frederick Laist and others presented to the American Institute of Mining and Metallurgical Engineers. We continue this abstract herewith.

Electrolytic Practice.—The tank house contains 864 cells divided into six units. The cells are 10 ft. 3 in. long, 2 ft. 10 in. wide, by 5 ft. deep. They are made of wood with a lead lining. Each cell contains 28 anodes and 27 cathodes. The anodes are made of chemical lead, and the cathodes of aluminium.

The authors give particulars relating to the effect of impurities in the solution.

In minute amounts, 10 mg. per litre of solution or less, copper does not appear to have much effect on the zinc deposit. In larger amounts, holes are eaten through the cathodes, leaving a black deposit on the aluminium surface; at times a bright deposit of copper is obtained. A second deposition of zinc will not take place until the aluminium sheet is thoroughly cleaned of the black deposit. If copper is the only injurious impurity present, the zinc deposit where not corroded will be firm and bright. High acids are conducive to active corrosion of the impure copper-zinc deposit. Copper attacks the surface of the aluminium sheet, which becomes so smooth that zinc will not adhere until it has been resurfaced.

Antimony is the worst impurity. The presence of any amount that can be determined (one part per 1,000,000) will give a very low current efficiency and a badly sprouted deposit, which results in low melting recovery. The deposit, when held to the light, shows a network resembling a lace curtain, and is lifeless, retaining any form into which it is bent without even partly recovering its original form. The presence of antimony in the zinc deposit has not been detected although present in the electrolyte in appreciable quantities.

The presence of 1 mg. of arsenic per litre in the electrolyte will make itself known at the end of 30 or 40 hours in a type of cathode corrosion peculiar to arsenic. The surface of the deposit becomes rough in appearance and loses its lustre. As this condition proceeds corrugations develop. Larger amounts of arsenic give a badly sprouted deposit similar in appearance to that caused by antimony. After completely re-dissolving the zinc deposit from a portion of the aluminium surface, a second period of deposition will begin, and as many as four depositions have been noticed for a single 48 hour period.

The presence of iron in the electrolyte in moderate amounts does not injure the current efficiency, although when oxidized it causes the aluminium cathode sheets to deteriorate rapidly and, therefore, it should be oxidized and precipitated in the neutral

leach and not allowed to overflow the neutral settlers. During the month of February, 1917, from 25 to 30 tons of chamber acid were added to the plant solution. The acid contained approximately 500 mg. of arsenic per litre ; it was necessary to add scrap iron to ensure arsenic removal. The iron in the purified solution at times was over 0·2 gm. per litre ; it averaged 0·13 gm. per litre for the month. Sufficient iron was oxidized in passing through the cells to provide the necessary ferric iron for arsenic removal. The electrolyte was of a greenish colour throughout the cell system, and apparently no permanganic acid or manganese dioxide was formed, as only about one-half of the iron was oxidized. After a month's trial, it was decided that, due to the deleterious effect of the iron on the aluminium cathodes, the continuous use of the high iron was not justified, although the plant averaged 89·3% current efficiency and yielded 12·3 lb. per horse-power-day for the month. The aluminium cathodes showed marked corrosion at the solution line and along the edges.

Manganese, in the absence of other impurities, has little, if any, effect on the zinc deposit. In the higher states of oxidation, as it exists in the cell, it aids re-solution of the deposit when started by other impurities. Pure zinc will dissolve more rapidly in cell solution than in pure dilute sulphuric acid, owing to the oxidizing effect of the manganese. Where cobalt is present in solution, it is claimed by other experimenters that at least a portion of the cobalt is precipitated by the manganese dioxide in the cell. It is also claimed that manganese protects the lead anodes from corrosion and that the deposit of manganese dioxide is beneficial. The authors insist that this manganese dioxide deposit must be removed at least once every six weeks.

The presence of 0·6 gm. per litre of cadmium in the electrolyte does not injure current efficiency or the character of the zinc deposit. To make grade "A" zinc, the cadmium must be under 20 mg. per litre in the purified solution.

Chlorine, in some forms, attacks the anode very violently when present in amounts of 50 mg. per litre or more. The cathode deposit does not appear to be affected by it.

Nitrates are undesirable as regards anode corrosion, especially in the presence of chlorine. The cumulative effect of the two is worse than either one alone.

Cobalt, nickel, tellurium, and selenium have not been investigated sufficiently to warrant definite statements. Sodium and potassium have no deleterious effect in moderate amounts when present as sulphates.

The corrosive effect of impurities increases greatly with the temperature. Since any re-solution causes an increase in temperature, and an increased temperature hastens re-solution, it is sometimes hard to tell which is the cause and which the effect. With slightly impure solution, it is possible to maintain a fair current efficiency if the temperature can be kept down ; this suggests the use of more cooling coils. With pure solution, a moderate rise in temperature, say from 35° to 70° C., does not cause a falling off in efficiency or change the character of the deposit ; more effort should be spent in purifying the solution instead of providing extra cooling.
